The Psychological Capital and Anxiety Felt by Post-Market Fire Disaster Victims

Dian Fitria, Mustikasari Mustikasari, and Ria Utami Panjaitan

Faculty of Nursing, Universitas Indonesia, West Java, Indonesia

ABSTRACT

Introduction: Traditional markets are a financial resource for traders. Fire disasters at the traditional markets will have a bad effect in terms of generating both financial and psychological problems. There is a lack of studies about the psychological problems experienced by traditional market fire victims. The aim of this study is to identify the correlation of psychological capital (hope, self-efficacy, resilience, and optimism) with the anxiety level among the victims of market fire disasters in Central Jakarta.

Methods: This study used a cross-sectional approach with a non-probability sampling method. This study involved 174 market fire victims from Central Jakarta. The independent variables were psychological capital, which includes hope, self-efficacy, resilience, and optimism. The dependent variable was anxiety level. The instruments used the Hope scale, the General Self Efficacy scale, The 14-item Resilience scale (RS-14), the Life Orientation Test-Revised (LOT-R) scale and the Generalized Anxiety Disorder scale. The data analysis used an Independent T-Test, Chi-Square, and multiple logistic regression prediction modeling.

Results: The more kiosks burned, the more that the informant's anxiety increased by about 4.845 times after applying a control factor of self-efficacy and optimism with a Wald value of 23.146.

Conclusion: Psychological capital (self-efficacy and optimism) have a significant correlation with anxiety in the market fire disaster victims. Good self-efficacy and optimism can reduce the level of anxiety felt. This study highlighted that psychological capital is a part of the disaster assessment as the basis for providing disaster nursing interventions.

INTRODUCTION

A disaster is an event that happens suddenly, creating damage, an ecological imbalance, a disrupted livelihood and worsening or even damaging people's health and the health services. A community will bear a huge burden and require external assistance (Landesman, 2014). The Centre for Research on the Epidemiology of Disaster (2016) stated that the Asian region is the area most impacted by disasters compared to other continents in the world (Guha, Hovois, Below, 2014). The natural condition and human behavior in Indonesia has placed Indonesia at number five based on the country's most impacted by disasters (Guha, Hoyois, Below, 2014). Disasters can be either natural or non-natural. Fire events are a non-natural disaster that occurs frequently. According to Jakarta's Central Statistical Bureau,

based on burnt objects in 2014, there were 1,260 fire events, and 238 among them were in public buildings. Industrial buildings and markets were included in this list. There has been a 100% increase from 2014 to 2015 for market fires. The Indonesian Market Sellers' Union reported that in 2014, there were 100 market fires. In 2015, there were 250. Therefore, in this paper, the researcher limits the disaster of focus to only non-natural ones with a specific focus on market fires.

Market fires occur for two reasons: old and inadequate buildings and sub-standard safety and security systems (Rarasati, 2013). The impacts of fire can be divided as follows: personal impact, loss of property, and a loss of service (Davidson, Price, McCauley, Ruggiero, 2013). Sixty five percent of post-disaster trauma originates from the loss of property. Market fire victims lose their property, which reduces

their economic functioning (Aslam & Tariq, 2010). The disrupted economic functions give way to psychosocial impacts in the form of anxiety for not having a livelihood (Knopp, 2016).

Several research studies have proven that anxiety is the biggest problem after a disaster. Psychosocial symptoms (66%) rank number two in terms of post-disaster problems after musculoskeletal problems (79%) (Nijrolder, Van der Velden, Grievink, Yzermans, 2011). Anxiety counts for 30 - 90% of post-disaster emotional trauma (Shoaf, 2014). Unmanaged psychosocial issues such as anxiety can worsen into depression, post-traumatic stress disorder (PTSD) and homicidal tendencies. Individuals with high psychological capital will succeed in improving their post-trauma living quality (Gail, 2013).

The resilience when facing a psychological impact due to disaster is highly influenced by the initial resilience "capital" and the initial psychological conditions possessed by each individual. This is called "psychological capital". Psychological capital is an individual's positive development related to the following characteristics: self-efficacy, positive attribution (optimism) and belief in reaching their target in life (hope). When stressors appear, they are able to persevere and survive (resiliency) (Luthans, 2007). Individuals with high psychological capital will be able to improve their post-trauma living quality (Gail, 2013). Based on these explanations, this study intends to examine the correlation between

psychological capital and anxiety in the market fire victims.

MATERIALS AND METHODS

This cross-sectional study encompassed 174 respondents recruited using the non-probability sampling. The respondents of this research were the victims of a market fire disaster living in a temporary relocation area who were willing to become a respondent. The researcher collected the data accompanied by the management staff of the traditional market, PD Pasar Jaya.

There were five instruments used in this study. Hope was measured using the Hope Scale questionnaire developed by Snyder and their colleagues with a reliability value of 0.897 (Snyder, Sympson, Ybasco, Babyak, Higgins, 1996). The General Self Efficacy Questionnaire with a reliability value of 0.925 was used to measure self-efficacy (Schwarzer & Jerusalem, 1995). The assessment of the level of resilience was done using the 14-item resilience scale (RS-14) with a Cronbach's alpha value of 0.81 (Wagnild, 1993). The optimism instrument used the Life Orientation Test-Revised scale (LOT-R) with a reliability alpha of 0.878 (Scheier, Carver, Bridges, 1994). The Generalized Anxiety Disorder questionnaire was used to measure the level of the respondents' anxiety with a Croncbach's alpha score of 0.92 and a reliability value of 0.83 (Spitzer, Kroenke, Williams, Lowe, 2006). All of the

instruments were translated into Bahasa Indonesian and a reliability value of 0.867 was obtained for this study.

The analysis of the research data was carried out through univariate analysis (central tendency and frequency distribution), bivariate analysis (independent T test and Chi-Square) and multivariate analysis (multiple logistic regression prediction modeling).

Ethical approval number 83/UN2.F12.D /HKP.02.04/2017 was sought from the Research Ethics Committee of the Faculty of Nursing, Universitas Indonesia. The data was collected through questionnaires and did not cause any harm to the respondents. The ethical requirements and respondent rights have been fulfilled throughout the research process.

RESULTS

The average age of the respondents was 35.94 years old (Table 1). Table 2 shows that the majority of respondents were male (55.2%), with the highest education level that of junior high school (42%). The most common response was being a market fire victim twice (51.1%) and the number of kiosks that had burnt most commonly totaled one (53%).

Table 3 shows the description of psychological capital in the majority of respondents with a mean score of 75.07 (SD = 10.39; 95% CI = 73.51-76.62). Self efficacy was 28.83 (SD = 4,180; 95% CI = 28,20-29,45), optimism was 36.43 (SD = 35.75-37.10) and having a high resilience was (47.4%) (Table 4). Table 5 describes that the majority of respondents experience moderate anxiety (66.7%) 3 months after the fire disaster.

The characteristics of the respondents' age and gender do not have a significant correlation with a p-

Four Kiosks	5	45.5	6	54.5	11	6.3	

value of 0.058 (Table 6) and 0.196 (Table 7). The number of kiosks burned and the frequency of being a market fire victim have a significant relationship with anxiety (P = 0.004; 0.000) (Table 7).

Table 8 shows that there is a significant correlation between self-efficacy and optimism with anxiety with a p value 0.015, 0.014. Hope and resilience do not have a significant relationship with anxiety with a p-value of 0.922 (Table 8) and 0.526 (Table 9). The more kiosks are burnt, the more that the victim's anxiety increases by 4.845 times after being controlled by self-efficacy and optimism.

DISCUSSION

The results of the research describe that age has no influence on the level of anxiety experienced by the fire market victims. This is due to the fact that age influences individual ego. However, it does not have any correlation with the anxiety experienced (Bonnet, 2007). Age does not have a correlation with psychosocial issues but it does have a correlation with the development stages (Baily, 2004). Age does not guarantee that an individual will have the ability to cope with psychological problems such as anxiety. This is because when people growing older, the ego can either grow up or not depending on the stressors encountered in their life, in the environment and related to their individual values. Age does not ensure that a person is adaptable. Each age-based life stage relates to developmental tasks that must be fulfilled.

The individual achievements that need to be fulfilled related to the developmental tasks influences the ability to solve the psychological problems present, not age.

Gender does not have a correlation with anxiety in the market fire victims. Based on previous studies, traumatic events like traditional market fires influence the ego and developmental tasks, not age. They also no relation towards their ability to solve the anxiety experienced. Gender has no influence on the anxiety experienced by individuals especially when referring to the specific cause of the natural disaster (Robbins, 2004). This research showed that gender has no relationship on a sudden traumatic event like a market fire disaster. It becomes acceptable that gender does not relate to anxiety. This is because the victims' ability to face an anxiety-inducing experience depends on the stressor that they have experienced previously, referring the environment, to developmental tasks, ego development and also religious values and their social life.

The number of burnt kiosks is a factor influencing the respondents' anxiety. The more kiosks are burnt, the more than their level of anxiety increases by about 4.845 times after being controlled by self-efficacy and optimism. Disasters and their impact are stressors for the victims. The stressors increase with the disaster-severity factor that is experienced, in addition to the disaster frequency and the scope of their losses (Math, Nirmala, Moirangthem & Kumar (2015). Material damage and associated losses will create

post-fire social and psychological problems. According to the research, there were three impacts as a result of the disaster; the personal impact, a loss of property and a loss of service (Davidson, Price, McCauley, Ruggiero, 2013). The amount of post-disaster material losses sustained caused 65% of the trauma (Aslam & Tariq, 2010). When the victims lost their products in the market, this meant that they lost financial resources as well. Material loss will affect to their family, social, financial and psychological life.

There was no severe anxiety level found in the market fire victims due to the grieving of the respondents being in the third phase. The stages of grieving are divided into the three phase. First there is the shock and numbness phase and then yearning, despair and disorganization as the second phase. The third phase is re-organization and recovery. This study was conducted 30 days after a market fire disaster, so the victims therefore have an ability to cope the resulting anxiety. The respondents also passed the acute stress syndrome phase that occurs 2 - 4 weeks after a disaster (Smid, Velden, Mulders, Knipscheer, Gersons, Kleber, 2013). After 30 days post-disaster, coping mechanisms will begin to emerge, according to the existing results of postdisaster management (Kaklauskas, Amaratungga & Haigh, 2009). Based on disaster recovery and reorganization by the management, they provide them with a new kiosk in the relocation area so then the fire victims can still receive transactions as a financial resource, which can relieve some of their anxiety.

Fire frequency and anxiety were found to have a correlation in the respondents studied. The research concluded that the disaster and its impact become a post-disaster anxiety trigger. This stressor worsens due to the factor of disaster frequency. These stressors increase with the level of disaster-severity factor that is experienced, inclusive of disaster frequency, and the scope of any losses (Math, Nirmala, Moirangthem & Kumar (2015). People who have experienced a disaster will experience psychological trauma. This worsens when the victims have successfully rebuilt their business and suddenly encounter the market fire disaster again. Their anxiety will be more than it was previously.

Psychological capital (self-efficacy and optimism) have a significant relationship with anxiety. The respondents' self-efficacy reached 75%, with another 25% needed to increase the self-efficacy value to the point where it is hoped to lower anxiety. Self-efficacy is the belief that the market fire victims possess related to their ability to successfully face a fire disaster. Therefore, the ability to find a way out by the respondents has improved through effort and reducing their negative thinking about the event. The respondents' optimism reached 72%, with 28% more needed to maximize the optimism possessed which is hoped to lower the respondents' anxiety. It can be said that the respondents have the ability to carry out certain activities in order to rise up following a fire disaster (Bandura, 1997). Improving optimism can be

done through the suppression of pessimism and practicing positive thinking.

The results show that there is no correlation between the psychological capital (hope, resilience) and anxiety. The current respondent is a merged survivor in a relocation area, so an adaptation response has been formed and processed within. Hope is therefore not correlated with anxiety. Hope does not have meaningful correlation with the anxiety experienced by the merged survivors (Ozag, 2006). Resilience does not have significant correlation with the anxiety experienced by the market fire victims. Resilience is not only individualistic. It is a combination of the robustness of the system, infrastructure, government, business, community, and individuals when it comes to withstanding, tolerating, absorbing and recovering (Briding, 2014). The resilience of the victim has been built by the PD Pasar Jaya as a form of management by providing infrastructure for the purpose of relocation with good compensation. The community of fire victims allows them to support, tolerate and recover alongside each other, so good resilience has been formed and processed by the community of the victim. Although they are supported by the community and PD Pasar Jaya, they still experience anxiety. This is the reason why resilience does not have a significant correlation with the anxiety experienced by the market fire victims.

CONCLUSION

Based on the results of this research, it can be concluded that there are two psychological assets with a correlation to anxiety: optimism and selfefficacy. Optimizing the respondent's positive assets can be performed by suppressing their negative feelings and practicing positive ones in order to find a way out. Hopefully, the results of this research can be used as an input for market administrators to allow them to provide health clinics for use by the traders. The Regional Disaster Management Board can coordinate with the local health office in order to establish a healthcare post for the health team, namely the role of post-disaster psychological nurse. The regional health office, together with the government, can optimize the community program through nurse mapping in community life. Therefore, market fire victims with psychosocial issues can be assisted at the community level. Further research can be performed to encourage the development of a nursing intervention based on the psychological capital.

ACKNOWLEDGEMENT

We extend our gratitude to PD Pasar Jaya, the Faculty of Nursing, Universitas Indonesia and STIKes RS Husada for their technical and related support.

Marital Adjustment and Prenatal Breastfeeding Efficacy of First Time Mothers in A Low-Income Community in the Philippines

Artemio Morado Gonzales Jr

Occidental Mindoro State College, Philippines

ABSTRACT

Introduction: All women should be offered support to breastfeed their babies to increase the duration and exclusivity of breastfeeding. This study aims to assess the level of marital satisfaction and its influence to prenatal breastfeeding self-efficacy in first time mothers during late pregnancy.

Methods: A descriptive correlational study was conducted among 128 systematically sampled primigravid women who agreed to participate and had prenatal care check-up in the health center at the time of data gathering. The instruments used were 15-item Marital Adjustment Test (MAT) to measure marital adjustment and 14-item Breastfeeding Self efficacy Scale-Short Form (BSES-SF) as a measure of breastfeeding self-efficacy. Pearson's correlation coefficient was utilized to test the relationships between the sample's marital adjustment scores to correlate with BFSE of the respondents. Fisher's t test was utilized to determine the significance of correlations. A p-value of equal to or less than .05 was considered statistically significant.

Results: The study revealed that the sampled mothers have a high level of marital adjustment score (112.05 \pm 21.83). Prenatal mothers responded in the study were highly confident and have high self-efficacy in breastfeeding first child currently bearing (4.55 \pm .51). Lastly, it was found that there is no significant correlation between marital adjustment and prenatal breastfeeding self-efficacy (β =-.052, p-value=.280).

Conclusion: It was found that there is a high level of marital adjustment and breastfeeding self-efficacy among sampled mothers. However, there is no significant correlation between marital adjustment and prenatal breastfeeding self-efficacy. The study suggests incorporating co-parenting intervention involving father's involvement and assistance with breastfeeding when creating interventions in breastfeeding.

INTRODUCTION

In 2012, the World Health Assembly Resolution 65.6 endorsed a comprehensive implementation plan on maternal, infant and young child nutrition, which specified six global nutrition targets for 2025 (World Health Organization, 2014). It urges developing or, where necessary, strengthening nutrition policies so that they comprehensively address the double burden of malnutrition and include nutrition actions in overall country health and development policy, and establishing effective intersectoral governance

mechanisms in order to expand the implementation of nutrition actions with particular emphasis on the framework of the global strategy on infant and young child feeding (Jones et al., 2014).

All women should be offered support to breastfeed their babies to increase the duration and exclusivity of breastfeeding. Support is likely to be more effective in settings with high initiation rates, so efforts to increase the uptake of breastfeeding should be in place. Support may be offered either by professional or lay/peer supporters, or a combination of both. Strategies that rely mainly on face-to-face

support are more likely to succeed (Renfrew, McCormick, Wade, Quinn, & Dowswell, 2012). Although health care professionals offer timely support to breastfeeding women (Bäckström, Wahn, & Ekström, 2010; Radzyminski & Callister, 2015), the more constant presence and immediate support of the baby's father, or mother's partner offers an opportunity to influence the maintenance and duration of breastfeeding. In a study with primiparous mothers, it revealed that high level of breastfeeding self-efficacy during postpartum predicted positive emotional adjustment and fewer depressive symptoms at six weeks postpartum, as well as more exclusive breastfeeding. On the other hand, breastfeeding concerns were among the most commonly named reasons for stress, along with lack of sleep, lack of social support, and overwhelming learning demands involved with being a new parent (Henshaw, Fried, Siskind, Newhouse, & Cooper, 2015). Also, many studies measure breastfeeding self-efficacy during early postpartum period (Chan, Ip, & Choi, 2016; McQueen, Dennis, Stremler, & Norman, 2011; Noel-Weiss, Rupp, Cragg, Bassett, & Woodend, 2006; Wu, Ho, Han, & Chen, 2018) and having less focus during prenatal period. There are studies focused on prenatal breastfeeding selfefficacy (McKinley et al., 2019), but evidence was limited to western countries and fewer studies conducted Asian mothers especially in the Philippine context

Father or partner has been identified as an influencing factor in maternal decision-making (Ghose et al., 2017). Mothers reporting positive support from their partners had higher confidence in breast milk production and higher breastfeeding self-efficacy. If the mother feels that the father's attitude toward breastfeeding is positive and supportive, there is a greater likelihood that she will continue breastfeeding (Mannion, Hobbs, McDonald, & Tough, 2013). This study aims to assess the level of marital adjustment and its influence to prenatal breastfeeding self-efficacy of the first-time mothers in late pregnancy period.

MATERIALS AND METHODS

Study design

The research design of the study was descriptive correlational to determine the relationship between marital satisfaction and the level of prenatal breastfeeding self-efficacy of the primigravid mothers. The assumption in this study is that marital satisfaction has an influence to prenatal breastfeeding self-efficacy, but there was no causal relationship assumed.

Study site

The study was conducted in the municipality of Rizal, Occidental Mindoro, which is considered a low income and third-class municipality. This area is near and accessible from the site in which many primigravid mothers receive prenatal care checkup with the healthcare provider.

Sample

A total of 128 primigravid women agreed to participate and had prenatal care check-up in the barangay health center at the time of data gathering. For each selected area, respondents were chosen using systematic sampling in the interval of 2. Inclusion criteria in the study were: 1) primigravid women, 2) pregnant women without known complication that may be contraindicated with breastfeeding, 3) pregnant women who were willing to participate in the research. The study assumes a 95% confidence interval, 50% expected frequency, design effect of 1 and a margin of error of 5%. The study needed 168 samples, but has a 76% response rate.

Instrument

The questionnaire was composed of three parts: socio-demographic section and the breastfeeding self-efficacy scale. The socio-demographic section includes age (ordinal); civil status (nominal); educational attainment (ordinal); income level (ordinal); number of prenatal visits (nominal).

The second part is the Marital Adjustment Test (Locke & Wallace, 1959), a 15-item scale that measures marital satisfaction. It was initially used to differentiate well-adjusted couples from distressed couples. The 15 items are answered on a variety of response scales and possible scores range from 0-158, showing higher scores indicate greater satisfaction.

The third part of the questionnaire was the 14item Breastfeeding Self efficacy Scale-Short Form (BSES-SF) by Dennis (2003). The BSES-SF is a selfsupport instrument containing two sub-scales: (1) the technique subscale, where items depict maternal skills and recognition of specific principles required successful breastfeeding; and (2)intrapersonal thoughts subscale, where 14 items are related to maternal attitudes and beliefs towards breastfeeding. Items are preceded by the phrase "I can always" and anchored with a 5-point Likert scale, where 1 means not at all confident and 5 means always confident. A study provided preliminary evidence that the BSES-SF may be an internationally applicable, reliable and valid measure to assist health professionals in caring for breastfeeding women. Cronbach's alpha coefficient for internal consistency was 0.87. Antenatal and postnatal BSES-SF scores were significant predictors of breastfeeding duration and exclusivity at 12 weeks after the birth (Alus Tokat, Okumuş, & Dennis, 2010).

Table 1. Profile of the respondents (n=128)

Profile	Frequency	Percentages	
Maternal age

2	25	19.5	
3	27	21.1	
≥ 4	54	42.2	

Data collection

Permission from the Municipal Health Officer was secured to conduct the study. Approved letter of request was presented to the rural health midwifes where the study was conducted. The coverage of the data collection started every Thursday of the month of November 2018 during the scheduled prenatal care visit in the Barangay centre. The data collection technique was through a survey interview using a questionnaire. The postpartum mothers were approached during visits in the Barangay Health Center. Informed consent was attained from the mothers before the researchers conducted the interview.

Ethical consideration

This paper was technically reviewed and approved by the Research Council of the Occidental Mindoro State College under its Research Development and Extension Unit. Participation in the study was voluntary and it was explained to the mothers that they have the option to answer the questionnaire or not. Complete anonymity of the research participants was observed. The respondents were informed of the right to confidentiality and privacy. Any clarifications were entertained by the researcher to facilitate easy understanding of the statement in the research instrument. The questionnaire was coded and listed in a separate sheet; the code from the list was later

matched after data collection. Specific information on the questionnaires could not be linked to specific individuals. Access to the data was limited only to the researcher.

Data analysis

Data collected were entered in Microsoft Excel and were analyzed with SPSS for descriptive and inferential statistics. Descriptive statistics used included percentages and frequencies demographic profile and mean for BFSE. Pearson's correlation coefficient was utilized to test the relationships between the samples' adjustment scores to correlate with BFSE of the respondents. Fisher's t-test was utilized to determine the significance of correlations. A p-value of equal to or less than .05 was considered statistically significant.

RESULTS

Data presented in Table 1 show that most of the young adults were aged 19-24 (45.8%). It also reveals that the respondents were unmarried (53.1%), reached high school graduate and high school and college graduate (both 25.8%), earning ≤ 7,890 and considered poor (66.4%) and most had met the national prenatal visit minimum requirement (42.2%).

The results (Table 2) show that the respondents have a high level of marital adjustment (MAT scores;

Prenatal BFSE	052	.280

^{*.} Correlation is significant at the 0.05 level (1-tailed)

112.05 \pm 21.83). Further, prenatal mothers who responded in the study were highly confident and had self-efficacy in breastfeeding their first child (4.55 \pm .51). It was also revealed that the respondents were both highly confident in breastfeeding technique (4.47 \pm .44) and intrapersonal thoughts on breastfeeding (4.59 \pm .52) (Table 3).

The study revealed that there is no significant correlation in marital satisfaction and prenatal breastfeeding self-efficacy (β =-.052, p value=.280). On the other hand, it also showed that there is a significantly negative and weak downhill linear relationship (β =-.148, p value=.047) between marital satisfaction scores and intrapersonal thoughts on breastfeeding among prenatal mothers in their late post-partum period.

DISCUSSION

Majority of these respondents were at their early adult age. In the Philippines, fertility peaks at age 20-24 and falls after 25-39 (Bersales, 2014). The findings on the current study also suggest that the majority of them did not pursue at aiming for the highest level of formal education. Studies have revealed that educated women are more likely to use maternal care services than women with no formal education period (Adu, Tenkorang, Banchani, Allison, & Mulay, 2018; Dutamo, Assefa, & Egata, 2015; Hill et al., 2013; Pulok,

Sabah, Uddin, & Enemark, 2016; Simkhada, Van Teijlingen, Porter, & Simkhada, 2008). According to the Philippine Statistics Authority, the national poverty threshold in 2015 is 10, 969 per month. Poverty threshold includes basic non-food needs such as clothing, housing, transportation, health, and education expenses (PSA, 2015). This indicates that the majority of the respondents were below poverty threshold. Population who belong to low income family could hardly afford to subject themselves to adopt the recommendations required for health improvement due to economic status (Bircher & Hahn, 2017). One study of peer counseling support shows that breastfeeding duration was significantly associated with increased maternal age and personal breastfeeding experience (Bolton, Chow, Benton, & Olson, 2009). A pregnant woman has at least one visit for the first and second trimester and two visits for the third trimester. Campbell and Graham (2006) supported this and stated that quality prenatal care is an important indicator for maternal and infant health status. If a mother is equipped with adequate knowledge in prenatal care, she is most likely to comply with the prenatal check-up and habits to attain maximum health during pregnancy.

The results show that the respondents have a high level of marital adjustment score. There was a statistically significant relationship between the perception of spouses toward their marriage or their

level of satisfaction with their relationship and being sensitive parents. The consistency in the relationship between spouses is also important for the baby to understand relationship connections (Mutlu, Erkut, Yildirim, & Gündoğdu, 2018). Further, it was also demonstrated that family functions, especially, problem solving, communications and family roles as well as marital adjustment, can explain more than half of the quality of life in women. Therefore, it is suggested that any intervention in increasing women's quality of life should take these aspects into consideration (Basharpoor & Sheykholeslami, 2015). Lastly, in a couple expecting their first child, both women and partners' coping behaviors contributed to higher marital adjustment, suggesting that risks for marital dissatisfaction may exist for couples not able to implement adaptive strategies, or for those unsatisfied with the implemented coping behaviors (Molgora, Acquati, Fenaroli, & Saita, 2019).

The results reveled that prenatal mothers who responded in the study were highly confident and had self-efficacy in breastfeeding their first unborn child. The results from the current study are consistent with the original BSES-SF study of Dennis (2003) and provide evidence that the BSES-SF is reliable measure of breastfeeding self-efficacy among a representative sample in Rizal, Occidental Mindoro. Pollard and Guill (2009) conclude that the score on BSES-SF was a statistically significant predictor of breastfeeding length. The use of the BSES-SF as the baseline assessment tool to identify women at high risk of weaning was also suggested. Using the BSES-SF as a screening tool, healthcare providers can target women at risk for early weaning and plan strategies that enhance mother's knowledge and breastfeeding using Dennis's breastfeeding self-efficacy framework. The BFSE-SF is also a useful tool in screening women who may need extra guidance and assistance once their children are born. If the individual leaves the class with a low self-efficacy score, the BSE-SF can be an effective tool in communication with breastfeeding support staff and lactation consultants in the clinic and hospital when the at-risk mother delivers and needs support and guidance in breastfeeding. Healthcare professionals can readily see the areas in which self-efficacy is low prenatally and help to empower the new mother to breastfeed successfully during the postpartum period. While previous research has found higher breastfeeding knowledge to positively impact both breastfeeding outcomes and breastfeeding intention (Cottrell & Detman, 2013; Kornides & Kitsantas, 2013), few studies have investigated the impact of breastfeeding knowledge on breastfeeding self-efficacy.

Lastly, the results revealed that there is no significant correlation in marital adjustment and prenatal breastfeeding self-efficacy. On the other hand, it also showed that there is a significantly negative and weak downhill linear relationship between marital satisfaction scores and intrapersonal

thoughts on breastfeeding among prenatal mothers in their late post-partum period. On the contrary, in other studies, it was shown that women who reported active/positive support from their partners scored higher on the BSES than those reporting ambivalent/negative partner support when we controlled for previous breastfeeding experience and age of infant (Abbass-Dick, Stern, Nelson, Watson, & Dennis, 2015; Mannion et al., 2013). The studies suggested that a co-parenting intervention involving fathers warrants additional investigation to assess significant improvements in breastfeeding duration, paternal breastfeeding self-efficacy, and maternal perceptions of paternal involvement and assistance with breastfeeding. Lastly, paternal involvement and paternal breastfeeding self-efficacy could increase the feeling of confidence to a breastfeeding mother (Abbass-Dick et al., 2015; Dennis, Brennenstuhl, & Abbass-Dick, 2018). This suggests conducting future studies to measure breastfeeding self-efficacy among fathers, especially in the prenatal period.

A limitation of this study was the fact that the sample of the study was composed of women who presented to outpatient clinics and this does not include the pregnant women who do not seek consultation in the Barangay Health Center. This research does not claim findings representative of all Filipino women. It is difficult to state that the sample used fully represented the sociocultural groups who live in the province. It is important to conduct further studies to test the psychometric properties of the scale in samples representing different groups. Also, this study was limited by its cross-sectional nature, as a result of which the relationships between marital adjustment sociodemographic variables, and prenatal breastfeeding self-efficacy do not necessarily indicate causal relationships.

CONCLUSION

The study shows that the respondents are young adult, unmarried, literate, considered poor, and receive minimum antenatal care. The results show that the respondents have a high level of marital adjustment. Prenatal mothers who responded in the study were highly confident and had self-efficacy in breastfeeding their first unborn child. Lastly, it was that there is no significant correlation in found marital satisfaction and prenatal breastfeeding selfefficacy. This study recommends to create intervention focused on maximizing psychosocial resources, mother-to-infant attachment and social support intervention to breastfeeding selfefficacy. There is also need to incorporate coparenting intervention involving fathers, which warrants improvements in breastfeeding duration, paternal breastfeeding self-efficacy, and maternal perceptions of paternal involvement and assistance with breastfeeding.

Self-Efficacy and Health Status in Coronary Artery Disease Patients

Wantiyah Wantiyah, Mochamad Riko Saputra, and Fitrio Deviantony

Faculty of Nursing, Universitas Jember, East Java, Indonesia

ABSTRACT

Introduction: Coronary Artery Disease (CAD) impairs all aspects of the patient's life due to the decrease in physical function and lower quality of life, indicating an overall decreased health status. Self-efficacy as a psychological factor plays an important role in individuals maintaining a healthy lifestyle and improving their health status. The aim of this study was to analyze the correlation between self-efficacy and the health status of coronary artery disease patients.

Methods: This study used an observational analytic research design with a cross-sectional approach. This study involved 112 respondents who were coronary artery disease patients in RSD Dr. Soebandi Jember obtained through the incidental sampling method. The data was collected using Cardiac Self-Efficacy (CSE) and Seattle Angina Questionnaire (SAQ). The data analysis used the Spearman rank test with a 95% CI.

Results: The results showed that there was a significant relationship between self-efficacy and health status (p = 0,001, r = 0.307, α = 0,05). Self-efficacy was in good category (71,41 points) while health status was also in the good category (79,56 points).

Conclusion: The low positive correlation between the two variables shows that the higher the value of self-efficacy, the higher the value of health status. Good self-efficacy through healthy living behaviors can increase the health status of coronary heart disease patients. It is important for nurses to improve the psychological aspect of the patients including self-efficacy when optimizing their self-care and health status.

INTRODUCTION

Coronary artery disease (CAD) is one of the most prevalent killer diseases in the world. The most common manifestations of underlying coronary heart disease are the presence of angina and myocardial infarction. Patients often experience symptoms of distinctive pain in the chest that spreads to the neck, jaw, ears, arms, and wrists, and possibly to the shoulder blades, back or abdomen. In connection with the effects of pain that are felt to be subjective, this can lead to psychological limitations such as anxiety arising from the sudden onset of illness and a fear of sudden death (Beltrame, 2017). Due to the feeling of pain, the physical restrictions, social disability, anxiety and depression, CAD patients are very vulnerable to a decline in health status (De Smedt et al., 2015; Le, Dorstyn, Mpfou, Prior, & Tully, 2018).

The symptom-based burden of CAD becomes the focus of attention because it is an impact that is felt directly by the patient (Stahle & Cider, 2018). The impact of the symptoms can cause physical limitations in terms of walking, climbing the stairs and other daily activities (Suputra, 2015). Healthy behavior must still be applied in order to maintain the stability of the health status of patients with heart disease (Nuraeni, 2016). Because CAD threatens the lives of sufferers in an ongoing manner, it needs there to be a good management of health continuously. CAD can be prevented through healthy lifestyle behaviors (Hendiarto, 2014). The psychosocial construct that plays a role in healthy behavior is self-efficacy. It is a strong predictor of the ability to adopt healthy

lifestyle changes (Bailey, Kashani, Eliasson, & Vernalis, 2013). Cardiac self-efficacy in cardiac patients is a specific measure of a patient's confidence in his capacity to perform activities that may be affected by the symptoms and complications of cardiovascular disease (Barham, Ibraheem, & Zyoud, 2019). Self-efficacy makes a difference in how individuals feel, think and act. The level of specific self-efficacy in cardiovascular health is related to important behavioral determinants of cardiovascular health such as a high-fat diet, physical activity, smoking cessation and high blood pressure control through active stress management (Wigger, 2011). In this case, self-efficacy can influence health behavior and chronic disease management in many chronic disease settings (Sarkar, Ali, & Whooley, 2007). Healthy behavior, as a major factor, can reduce the risk of disease from becoming more severe and increase the success of any treatment and surgery that is to be performed (Nuraeni, 2016)

Research findings in the United States show that on average, CAD patients have less self-efficacy. This low level of self-efficacy is associated with the risk of poor health management (Sarkar, Ali, & Whooley, 2009). Poor health management behavior is also indicated by poor dietary arrangements and irregular returning control after home following hospitalization (Wantiyah, 2010). CAD patients with lower initial self-efficacy are more likely to be hospitalized for heart failure. In fact, with each standard deviation (22%), the decrease in the participants' self-efficacy is 40% more likely to resulting in them being hospitalized with heart failure and they are 30% more likely to die (Sarkar et al., 2009). In addition, low self-efficacy involves many of the risk factors for existing heart disease. This is indicated by the research involving 71 respondents; 81.6% of the respondents (as many as 58) had low self-efficacy with many of the risk factors (Bailey et al., 2013)

Coronary artery disease is a chronic disease that lasts for the duration of a patient's life that is able to cause fluctuations in their health status from optimal function through to dropping dramatically due to recurrence. This can be life threatening (Wantiyah, 2010). This disease requires complex treatment management including not only medication adherence but also a healthy lifestyle. Self-efficacy is important in the management of CAD because it comes from the individual who feels the impact of the disease. This is improved through the motivation to change into having a good level of health management and decision making in reference to their care (Hendiarto, 2014; Riegel et al., 2017). The ability to manage their lifestyle as a form of good self-efficacy is needed, especially when managing their exposure to risk factors. People tend to ignore this and have unhealthy lifestyles such neglecting to lessen the sodium in their diet and eating high-lipid foods. These both have an impact on the development of cardiovascular disease. This study hypothesis is that

self-efficacy has a correlation with perceived health status among patients with CAD.

MATERIALS AND METHODS

This study used an observational analytical design with a cross-sectional approach. The sample used in this study consisted of CAD patients post-outpatient treatment in the Heart Clinic of RSD Dr. Soebandi Jember. In total, 112 patients with CAD were selected as the research participants according to the criteria established by the researcher. The measurement of the sample size used the application of G * Power with a power analysis of 0.90.

The sampling technique used in this research was incidental sampling. This sampling technique determined the sample based on coincidence, where anyone who incidentally meets the researcher and who fits the inclusion and exclusion criteria can be sampled (Nursalam, 2017; Sugiyono, 2016). The data

collection process was carried out in January 2020 in the Heart Outpatient ward of RSD Dr. Soebandi Jember. The process of taking the data used an instrument in the form of a demographic characteristic questionnaire. The self-efficacy measurement was done using the Cardiac Self-Efficacy (CSE) questionnaire by Sullivan translated and adapted to Bahasa Indonesian. This was found to be valid and reliable with a Cronbach's Alpha reliability of 0.77 (Wantiyah, 2010). The health status measurement was done using the Indonesian version of Seattle Angina Questionnaire (SAQ). The validity and reliability values in general for the SAQ questionnaire were in the range of 0.477-0.577 and the Cronbach's Alpha value was 0.866 (Nurhalimah, 2016). The data analyses used a Spearman rank test with a 95% CI by using SPSS 26 to determine the relationship between the two variables, namely selfefficacy and health status in patients with CAD.

This study was declared to have passed the ethical test conducted by the Health Research Commission of the Faculty of Dentistry at the University of Jember with Ethics committee approval number No. 706/UN25.8/KEPK/DL/2019. All of the respondents in this study were given informed consent. The study respondents had the right to refuse to participate without penalty if they wished to do so.

RESULTS

The respondent's demographic characteristics including age, gender, education, occupational status, income, marital status, history of disease and history of heart attack in the past month have collectively been displayed in Table 1. Based on Table 1, most of the respondents (81.25%) were men. The respondents were dominated by those in the age range of 55-64 years, totaling 61 respondents

(54.47%). The most common educational history of the respondents was having graduated Senior high school, totaling 45 respondents (40.18%). Most respondents did not work, totaling 53 respondents (47.32%). In relation to this, 63 respondents (56.25%) earn more than Rp. 2,000,000.00. Almost all of the respondents are married (92.9%). The respondents' smoking history shows that 77 respondents (68.8%) have a history of smoking and that 48 respondents (42.86%) have hypertension. Chest pain experienced by the respondents during the past month showed that as many as 81 respondents (72.3%) did not complain of a heart attack in the past month.

In Table 2, the self-efficacy measurement by CSE shows an average value of 71.41 (SD: 5.45). In Table 3, the health status measurement by SAQ shows an average value of 79.56, which indicates that the average health status of CAD patients is included in the good category because the criteria value \geq 72.03 is the natural cut-off point. The median value is 80.39 with a minimum value of 49.06 and a maximum value of 95. It is known that the indicator with a high average score has a symptom load of 89.9 with a minimum value of 20 and a maximum value of 100. The indicator with the lowest average value was physical limitations, equal to 68.4 with a minimum value of 20 and a maximum value of 100.

Table 4 shows that there is a correlation between self-efficacy and health status in CAD patients. The Spearman rank test correlation coefficient value of 0.307 shows that the correlation category of the relationship between the two variables is low. The direction of the relationship shows there to be a positive value which means that the higher or better the self-efficacy, the higher or better the health status of the CAD patients.

DISCUSSION

This study found that there is a relationship between self-efficacy in reference to the ability to manage the changeable risk factors with health status. The study findings show that good self-efficacy has a positive effect on the perception of the health status of CAD patients. This can impact their condition and any improvements. The improvement is indicated by the low complaint of angina recurrence and other symptoms of a heart attack. The level of specific self-efficacy on cardiovascular health is related to the important behavioral determinants of cardiovascular health such as a high-fat diet, physical activity, smoking cessation and high blood pressure control through active stress management (Wigger, 2011).

The statistical analysis results show that there is a relationship between the self-efficacy variable with the variable of the health status of CAD patients. The correlation category shows that the relationship between the two variables has a low correlation. The relationship between the two variables has a positive relationship. The nature of the relationship shows that good self-efficacy associated with health

management will have an impact on the better health status of the CAD patients. This is supported by the research by Ahn, Song, & Choi, (2016) which shows that there is a relationship between the variables, where self-efficacy, self-health behavior and the risk factors that can be changed have an important role in improving the quality of life of CAD patients through better and effective management of cardiovascular risk factors. Research by Sarkar, Ali, & Whooley (2007) shows that among patients with CAD, low cardiac self-efficacy is associated with poor health status, independent of CAD severity and depressive symptoms. The lack of self-efficacy in cardiac patients is associated with good selfacceptance. Individuals who have good selfacceptance can mean that they can accept both their weaknesses and strengths with realistic expectations. They can respect themselves. Individuals claim to be able to accept their conditions in various aspects positively and be able to live life well (Puspita, 2018). According to Bandura (1994), good self-efficacy is able to bring in adaptive behaviors, especially in the prevention of a health problem. Preventive efforts that are intended are efforts to reduce or control the risk factors that are detrimental to health. These efforts include being physically active, maintaining blood pressure, and developing various ways to manage stress (Buchanan, 2016).

The low correlation of the two variables as indicated by the findings of the study in some patients showed good self-efficacy but a poor level of health status. These results are irrelevant because the patient's self-efficacy began to be high after they were diagnosed with CAD, especially in new patients. It is known that CAD is a disease that is caused by a long period of exposure to the risk factors. A drastic change in self-efficacy when the patient changes his behavior in terms of health management and risk exposure does not show significant results in terms of improving their health status immediately.

CONCLUSION

Based on the research findings and discussion, it can be concluded that there is a relationship between selfefficacy and health status in patients with coronary heart disease at a low correlation level. The results showed that the better the self-efficacy of the patients with coronary heart disease, the better their health status.

Prospective studies can explore, using qualitative methods, matters related to self-efficacy and health status including the patient perceptions related to the symptoms and limitations in terms of CAD given how the opinions, ideas and assumptions will be broader than just the symptoms themselves.

ABSTRACT

Introduction: Increasing the life expectancy of the elderly raises complex problems concerning the life aspects of the elderly, family, community, and government. A well-being indicator for the elderly is needed as a measurement tool to facilitate Indonesian elderly individuals to becoming more prosperous. The purpose of this study was to develop well-being indicators and to formulate the elderly well-being Index.

Methods: This study used an explanatory research design with a quantitative approach. In total, 400 respondents were collected using multistage random sampling. The physical well-being variable used the Mini-Mental State Examination (MMSE) instrument, Barthel's index, and the Disease Complaint questionnaire. In addition, a psychology and social well-being instrument, social well-being instrument, and spiritual instrument were employed. Confirmatory Factor Analysis was used to verify the factor structure of all of the observed variables.

Results: The results showed that the indicators for elderly well-being are demographic with the following factor loading: (λ) 0.32, social environment (λ)=0.51, health services (λ)=0.55, physical well-being (λ =0.36 psychological wellbeing $(\lambda)=0.46$, social well-being $(\lambda)=0.45$ and spiritual well-being $(\lambda)=0.50$. The indicators and index can be used as an effort to drive the program, so then the elderly can become productive, prosperous, and meaningful.

Conclusion: The elderly well-being index is expected to be a programmatic instrument that can measure and evaluate the welfare of the elderly. This will increase the elderly health program that is available to achieve more holistic wellbeing and an age-friendly city.

INTRODUCTION

A growing elderly population has an impact when trying to improve the quality of life. Human wellbeing is one of the most popular fields of modern multidisciplinary research. The issue is topical due to the conclusions that it is on economic and social change. More than 25% of the world population will fall into the category of being elderly by 2050 (Global Age Watch Index, 2014). This also has an impact on the increasing growth of Indonesia's elderly population. The increase in aging is estimated to

reach 63.31 million in 2045, which is around 20% of the population (Bps, 2018). Elderly needs are not only related to meeting their physical and financial needs that are currently the focus, but it also refers to their overall needs in life. At present, the increase in the number of elderly residents is not accompanied by an increase in the well-being of the elderly (Lifshitz, Nimrod and Bachner, 2019).

The view of well-being lies in the approach used in interpreting well-being. Well-being starts from the study of social and economic perspective approaches, where social well-being is a state of human life that is created when facing various social problems that can be managed properly (Fave et al., 2018). The wellbeing study in this research uses being 60 years of age and over to refer to the elderly, which includes their physical, psychological, social, and spiritual wellbeing. The elderly group that is the target of this development is also the concern of the Surabaya city government (Bps, 2018) of East Java. At present, the problem of the elderly is the focus of a study conducted by the province of East Java, especially the city of Surabaya. One of the development goals in East Java is to improve the well-being and quality of life of the people, including the elderly in East Java. In line with that, the formulation and direction of development policies are aimed at empowering and improving well-being. However, the program's achievements are not yet clear. The concern for older individuals about their well-being is closely related to their health condition. As an individual get older, their health declines and may worsen due to the constraints faced when maintaining their health (Ivankina and Ivanova, 2016). At present, the Indonesian government has launched an elderlyfriendly city program (Hermawati, 2015). The acceleration program for achieving an elderlyfriendly city is one of the efforts undertaken to anticipate the explosion of the elderly in Indonesia by 2035. The explosion will have an impact on the socioeconomic burden of the state (Global AgeWatch Insight, 2018).

The Indonesian government does not have any indicators, nor an index prepared to measure the well-being of the elderly. Well-being indicators use individual income guidelines, but this was a different concept between welfare and well-being (Wiliyanarti et al., 2017). The availability of appropriate indicators will help the Indonesian government determine the scale of the priorities and targets of well-being development. If there are no indicators or well-being indexes available, the government will experience difficulties when trying to determine the well-being category of the elderly for certain individuals or regions (Wiliyanarti, Asri and Putra, 2018). This will have an impact on the development of the elderly well-being program. It is important to understand that index numbers do not only measure a variable or indicator. They can measure several indicators at the same time. Advances in technology and knowledge require an effective method to be able to find a change in relation to the welfare of the elderly (Wiliyanarti, 2018). An index number is a simple statistical measure that can indicate a difference in the individual (elderly), so then the value and category of the index are known.

Based on the concept of health, according to Fleuret and Atkinson (2007), it conveys that well-being is a perfect state that includes physical, mental, social, and spiritual well-being. It does not mean being free from disease only. This indicator does not mention in detail the symbols used for each component, making it difficult to measure the achievement of well-being because it is still too

general. The well-being of the elderly in various regions has not been measured using the same indicators.

Therefore, in order to be able to assess the level of well-being of the elderly, it is recommended to use the elderly well-being index as an additional method paired with the use of the existing indicators. The availability of appropriate indicators will assist the government in determining the scale of the priorities and targets of well-being development. If there are no indicators or well-being indexes, the government will have difficulty identifying the well-being categories of the elderly for certain individuals or regions. This will have an impact on the development of the elderly well-being program. The study aimed to develop the elderly well-being indicators and subsequently to formulate the Elderly Well-being Index in Surabaya.

MATERIALS AND METHODS

This study aimed to develop indicators for the well-being of the elderly. The research was conducted in two stages. The first stage used a qualitative approach presented in the form of a descriptive exploration (Burhan Bungin, 2005).

The study design used was an explanatory research study with a cross-sectional approach. The population was all of the elderly living with families the study conducted in a selected village in the city of Surabaya. The sample was in the working area of the primary health care services of Surabaya (East, West, Central, North, South), totaling as many as 400 respondents. The sampling method used in this study was Multistage Random Sampling. The research variables were physical, psychological, social, and spiritual well-being. At the quantitative research stage, the research instruments were in the form of structured questionnaires. The instrument was created after the first research phase was completed when the indicators had been collected qualitatively. The indicators that were collected were used as for instrument development. material instruments used were for physiological well-being (Ryff, 2014), social well-being (Ryff, 2014), and spiritual well-being (Gomez and Fisher, 2016). Modifications in terms of the instrument theme studies are associated with elderly well-being. The indicators tested for validity and reliability were psychological well-being with a value of 0,691, social well-being with a value of 0.7, spiritual well-being with a value of 0.971, social environment with a value of 0.7 and the health service factor with a value of 0.8. The instruments that were not tested for validity and reliability were the indicators for the demographic factors and physical well-being. This study was approved by the Ethics Committee number 37-KEPK in 2016.

RESULTS

Based on Table 1 above, it is known that the majority of the elderly were aged 60 - 69 at 68.3%, that women made up 80.8%, and that the percentage for those not

Table 1. Characteristic of Respondents (n=400)

60 - 69 years old	273	68.3
70 - 79 years old	113	28.3
> 80 years old	14	3.5
Gender		
Man	77	19.3
Woman	323	80.8
Income status		
Have an income	133	33.3
Don't have an income	267	66.8
Expenditure		
Expenditure 40% of income	135	33.8
Expenditure 41% - 60% of income	143	35.8
Expenditure >60% of income	122	30.5
Occupation		
Working	87	21.8
Un-employed	313	78.3
Marital status		
Married	254	63.5
Divorced	14	3.5
Widow/widower	128	32.0
Un-married	4	1.0
Education		
No education	27	6.8
Elementary school	107	26.8
Junior High School	96	24.0
Senior High School	95	23.8
Diploma	23	5.8
Bachelor's	51	12.8

working was 78.3%. The percentage of those who had no income was 66.9%, and 63.5% were married. Expenditures most commonly made up 41% - 60% of any income, and the most common level of education was 26.8% for elementary school.

Based on table 2, the factor loading value of the 27 valid indicators, the factor score was calculated (Table 2). Based on the data above, it can be seen that out of the seven indicators. All indicators have a factor loading value above 0.3. The Confirmatory Factor Analysis (CFA) model for elderly well-being showed that the indicators that have the highest factor loading value were health services (X3=0.55) spiritual (Y4=0.50), social services (X2=0.51), psychological (Y2=0.46), social (Y3=0.45), physical (Y1=0.36), and demographics (X1=0.32).

The results are known to all of the indicators with a factor loading value >0.4 or value of t λ > 1.96 (α = 5%). Thus, be concluded that the seven indicators above are valid to use to measure the well-being of the elderly. Based on the results of Table 3, the Elderly Well-being Index Formulation can include the addition of 0,3(X1) + 0,51(X2) + 0,55(X3) + 0,36(Y1) + 0,46(Y2) + 0,45(Y3) + 0,50(Y4), after which the index value is categorized. The categorization of prosperity is 15.50 - 19.35, while well-being is sufficient 19.36-23.20, and prosperity is 23.21-27.05 (Table 3).

DISCUSSION

The indicator of demographics can be explained by education and income. The education achieved by the elderly contributes to the perception of the elderly regarding well-being. The income of the elderly made it known that most of the elderly do not have an income. Meeting their needs in everyday life is a cost borne by the family (Bps, 2018). For the elderly individuals that do have an income, this shows that there are still elderly who are actively working to fulfill their daily needs, or just to fill their spare time. They may also have a pension fund (Hyde, Maher and Elavsky, 2013). The ability of the elderly to meet their daily needs and to be able to help other families is an old formula for financial happiness (Kirkwood and Cooper, 2014). The elderly in the community have different well-being levels depending on if the elderly can adapt and go through the aging process.

The health service indicators explained that health services had become one of the components in the well-being of the elderly. The factor loading meets the standard criteria. It can be stated that the social environment and service guarantees are the indicators of the well-being of the elderly. According to the research, the social environment being optimal is a condition that is needed by the elderly (Burton, Mitchell and Stride, 2011). The environment determines the achievement of well-being for the elderly. Health insurance is one of the health efforts that the elderly need. When the elderly individual becomes sick, fulfilling health insurance is needed. The elderly health services in Indonesia are facilitated by the existence of the Elderly Health Services Post. The benefits of the Health Services Post for the elderly that it was a community-based service effort, among others. It seeks to improve the health status of the elderly, increasing their independence, slowing the aging process, and allowing for the early detection of health problems and increasing their life expectancy (Erpandi, 2015). The elderly way of life in the environment is very influential in the development of the elderly. The environmental conditions can provide support to increase the interest of the elderly to achieve a better sense of overall well-being (Wiliyanarti, Notobroto and Asri, 2017). A thriving environment is an environment that can improve the physical health, psychological well-being and social needs of those within it (Othman and Fadzil, 2020)

Successful or optimal old age emphasizes that the elderly have three relevant components: avoiding disease, the ability to work, and the ability to interact socially. The existence of disease is an indicator of the physical well-being of the elderly. This was stated by several elderly (Hyde, Maher and Elavsky, 2013). The physical condition is affected by the disease, which can reduce the life satisfaction of the elderly. Physical functioning and elderly cognition are also indicators of physical well-being. Changes in the organic and systemic systems vary greatly, both between individuals and within individuals as well (Kirkwood and Cooper, 2014). Aging with chronic stress can

Table 2. Well-being Indicators based on Loading Factor

Factors	Indicators	Factor Loading (λ)
Demography	1. Level of expenditure	0.41

	3. The environment	0.88
	4. Communal	0.91

reduce immune function, making the elderly more vulnerable to getting an infection. The digestive system can still be quite efficient even though the elderly are more at risk of malnutrition. The elderly have a heart functioning level that is slower and irregular, often due to the occurrence of obesity in the elderly. This also increases blood pressure (Kirkwood and Cooper, 2014).

Nevertheless, there are still many elderly individuals who do not pay attention to the changes in their systemic functions. The elderly abilities related to cognitive function also experience changes, but not all changes in the brain are destructive. Changes in cognitive function are not fundamental, and they do not significantly affect cognition, although there are increased brain changes. Cognitive decline tends to increase (Papalia, Olds and Feldman, 2009). The physical activity carried out by the elderly is closely related to the level of well-being, normally referring to the activities carried out by individuals without assistance. However, this was different for each age group where the elderly experience physical decline (Hyde, Maher and Elavsky, 2013). This was also stated by (Roberts et al., 2017), who stated that the ability to carry out basic activities could be used to refer to the continuation of old age and the desire to remain independent and to have a good quality of life. The ability to work independently contributes significantly to the quality of life of the elderly, and it is associated with psychological well-being (Fave et al., 2018).

Psychological well-being, in general, can be interpreted as a form of satisfaction with aspects of life to bring in or cause feelings of happiness and a

feeling of peace in one's life. The standard of satisfaction in each person is different, so this is subjective. Based on the results of the study, all of the indicators for psychological well-being can be used to measure psychological well-being, proving that the loading factor's statistical value is above the standard value. (Ryff, 2014) states that a positive attitude, which is a component of psychological well-being, is needed to recognize and accept the various aspects of the self, both positive and negative. They should have positive feelings about their past life. Self-acceptance means that the elderly are able to reflect on the shortcomings that exist in their elderly self. It was included the weakness of the physical condition when aging. This should not be a thing that reduces happiness, but instead, it should result in the sense of acceptance in the form of gratitude. The purpose of life that is possessed by the elderly is also an indicator and component of psychological well-being. Ryff formulates psychological well-being into multidimensional model (Ryff, 2014). dimension describes the efforts made by someone to face different challenges, then the individual functions positively. Individuals who are autonomous means that the individuals have a sense of selfdetermination and that they are free and able to overcome social problems by thinking and acting according to their beliefs. They regulate their behavior from within and evaluate themselves based on their standards. Psychological well-being must be supported by mental health, which is not only about being without a mental illness. Positive mental health involves psychological feelings of well-being that coexist with self-health (Ryff, 2014). Suggested health

Table 3. Significance of the CFA model on Elderly Well-being

Symbol & Variables	Factor Loading (λ)	tλ	1-δ	t _{1-δ}
X1. Demography	0.32	4.49	0.90	13.47
X2. Social environment	0.51	8.63	0.74	11.44
X3. Health services	0.55	10.14	0.70	
Y1. Physical well-being	0.36	6.20	0.87	
Y2 Psychological well-being	0.46	7.63	0.79	12.15
Y3. Social well-being	0.45	7.50	0.80	12.23
Y4. Spiritual well-being	0.50	8.36	0.75	11.65

and social policy approaches include supporting ameliorating an older adults' disability stages which may also contribute to their improved social life and mental health. Preventing functional decline may help to maintain regular social participation and independence in terms of mobility. (Stage 0) seems to be crucial to mental well-being. Psychosocial support should be allocated to individuals in higher ADL stages because of their more significant mental health needs. The findings from this study emphasize the salience of the care coordination required to provide complete medical, rehabilitative, psychological, and social care (Na and Streim, 2017).

The social changes that occur in the elderly are related to the physical and cognitive changes experienced by the elderly. Entering a happy old age is the same as being prepared to face changes in all aspects of their life. Social change can be a source of stress if it is not responded to positively (Fave et al., 2018). Many elderly can remain optimal in the social field, and they can achieve conditions that are said to be prosperous (Elo and Isola, 2011). The results of the social well-being Confirmatory Factor Analysis model show that the indicator that has the highest factor loading value was a social contribution. A small loading value was excluded from the model, referring to social relations and social integration. The social well-being indicators are based on the statistical test results for social contribution, social relations, and social inclusion. The results obtained a loading factor result that was more than the standard indicator. Based on these results, it appears that the elderly have both carried out their social roles in the application of daily life, and they have value in the community. The research conducted by Seligman (Diener and Ryan, 2008) shows that the happiest people have good quality social relationships. Relationships that are considered to be useful must include two of the following three social relationships, namely family, friends, and harmonious relationships. Elderly social relations and social integration with the environment are positive behaviors in the environment (Wiliyanarti, Notobroto and Asri, 2017). Most of the elderly can fully interact in society, but the intensity of each individual's interactions shows a difference in the sense that the social relations carried out by the elderly occur only when due to a program or association (Wiliyanarti, Notobroto and Asri, 2017). It also found that the elderly who become cadres and who are active feel happy at being able to socialize. Therefore social relations and social integration cannot yet be a

measure to show that these indicators are the components of the social well-being indicators. Elderly well-being is in line with the quality of life, as well as the amount of social relations experienced (Ivankina and Ivanova, 2016).

Spiritual activity is something that can be said to be synonymous with old age activities (Gomez and Fizer, 2016). In societies in various countries, some elderly are made spiritual leaders in various religions, including churches, Muslim communities, and others. Based on the results of research conducted looking into the characteristics of spiritual well-being, the aspect of approaching God and the personal, environmental and communal aspects are in the good category. In this case, it can be interpreted that almost all elderly have fulfilled the criteria for spiritual happiness. The results of the spiritual well-being model show that the well-being components above are declared to be valid. The highest factor loading value is the God indicator. This is in line with spiritual well-being, according to (Gomez and Fisher, 2016). They stated that something is felt about the positive reflections on their behavior and cognition relating to oneself, in addition to society, intuitive feelings and the environment, the ability of individuals to identify themselves alone, commitment, positive attitude, and hormones in life. They also state that the reason for participating in religious activities is related to one's well-being (Diener and Ryan, 2008). A religious belief system helps most people to deal with stress and loss across the life cycle, providing optimism that the later life problems that cannot be overcome today will be resolved. In line with the opinion of (Diener and Ryan, 2008), the relationship between religion and the practice of spirituality is paradoxical. A religious person tends to have a higher sense of well-being, and it is more specific about matters of participation in faithful service, affiliation, a relationship with God, and praying. Older people get a better appreciation of the meaning of life from religion, as well as life satisfaction, self-esteem, and higher optimism (Lifshitz, Nimrod, Bachrur, 2009).

The use of this index can be preventive and part of an evaluation related to the well-being of the elderly in Surabaya. The use of indices in both the municipal and central governments. It is useful for measuring the well-being categories of each region. The areas with low elderly well-being categories are to be used for an evaluation of the elderly well-being programs. Based on the results of the study, it can be noted that the Surabaya urban elderly well-being index has an average value. It can be declared that the elderly in

Surabaya are in the prosperous category. Based on the formulation of the well-being index of the elderly, it is known that the most significant contribution is that the elderly can be biased in terms of well-being, environmental factors, health services, and spiritual well-being. In line with (Fleuret and Atkinson, 2007), they state that achieving success with the well-being index of the elderly must be supported by all aspects of life. The elderly can prepare themselves to face old age in a manner that is prosperous, productive, and meaningful. The strategy to become a friendly city for the elderly in 2030 requires an improvement of the indicators that achieved low, which does not require a lot of money. The results of this study can be used as input in the data assessment. Reconstruction is needed to plan towards having an elderly-friendly city (Kemenkes RI, 2013).

The limitations of the study were the sample consisted of the elderly, who live with their families. It did not include the elderly in nursing homes or the elderly who are being treated in hospitals. The measurement of the indicators for physical wellbeing is limited to the instruments of daily ability. Psychological well-being also did not look at the level of depression in the elderly.

CONCLUSION

Based on the above results, the indicators of elderly well-being are demographics, the health services available, the social environment, physical well-being, psychological well-being, social well-being, and spiritual well-being. The well-being indicators are expected to be a measuring tool that is a component of the well-being index. This study was useful as an evaluation of the elderly well-being in a manner that can be applied to policies and programs to improve the health of the elderly in both the regional and central government areas. The results can be used as a tool for improvement related to the elderly program to make the age-friendly city more optimal.

The Relationship Between Fulfilment of Basic Needs with the Incidence of Stunting In Toddlers

Endang Surani and Endang Susilowati

Sultan Agung Islamic University, Semarang, Central Java, Indonesia

ABSTRACT

Introduction: The prevalence of toddlers who very short and short at the age of 0-59 months in Indonesia is still high. One cause of stunting is lack of nutrition, mainly in the first 1000 days of life. The purpose of this study was to identify the relationship between the fulfilment of basic needs with the incidence of stunting in toddlers.

Methods: A quantitative analytic research methods using cross-sectional approach was applied on this study. The sample was100 toddlers collected by purposive sampling technique. The questionnaires were used to measure the fulfilment of the basic needs of children and included questions about physical, emotion and stimulation. The data were analysed using Chi-Square.

Results: There was a relationship between fulfilment of the basic needs in physical and emotion category with stunting (p value of 0.000), while there was no relationship between fulfilment of basic needs in the category of stimulation with stunting (p value of 0.090).

Conclusion: The fulfilment of the basic needs of physical and emotion affects the condition of toddlers with stunting. Thus, all of children should get exclusive breastfeeding, appropriate complementary feeding, early childhood education programme, attend an Integrated Healthcare Centre routinely, have adequate access to immunisation services.

INTRODUCTION

More than two million deaths of children under 5 years in the world are directly related to malnutrition, especially wasting and stunting. According to data released by UNICEF, there are around 195 million stunted children who live in poor and developing countries (Wiyogowati, 2012). The World Health Organization (WHO) placed Indonesia as the third country with the highest stunting prevalence rate in Asia in 2017, reaching 36.4%. However, in 2018, the figure continued to decline by 23.6%. From the same data, it is also known that stunting in children under five in Indonesia dropped to 30.8%. In Indonesia in 2017, the prevalence of toddlers was very short and short at the age of 0-59 months by around 9.8% and 19.8%, respectively and, in 2018, around 30.8% of toddlers were in the very short and short categories

while in Central Java Province in 2018 it was around 31.22% (Riskesdas, 2018).

Stunting is a syndrome in which linear growth failure functions as a marker of several pathological abnormalities associated with increased morbidity and mortality, loss of potential for physical growth, reduced nerve development and cognitive function and increased risk of chronic disease in adulthood (Kemenkes, 2018). Stunting can occur as a result of malnutrition, especially in the first 1000 days of life. There are multidimensional factors that cause stunting, including poor parenting practices, limited health services including ante natal care, lack of access to nutritious food, lack of access to clean water and sanitation (Kemenkes, 2018).

The nutritional status of children less than five years old is very influential in the process of growth and development. In stunting children there is a growth failure (growth faltering) that starts in the womb and lasts until the child is 2 years old. This problem can occur due to lack of protein energy as one of the main nutritional problems that occur in toddlers and which is very influential on the child's growth and development process (UNICEF, 2010).

One treatment that can prevent the occurrence of stunting in children is to meet the basic needs during growth and development, namely fostering, caring and homing needs; these basic needs affect nutritional status. Basic needs greatly affect the nutritional status is the fulfilment of fostering needs because it is directly related to the physical environment of children (Maria & Adriani, 2009).

Parenting is a way parents treat their children by looking after, caring for, and educating them. From the way the parents treat them it will reflect their own characteristics which will affect the child's attitude patterns later on. Basic needs are very necessary to support the growth and development of children. These basic needs can be grouped into three, namely "asih, asah, and asuh" (Soetjiningsih, 2013). The purpose of this study was to determine whether there is a relationship between meeting basic needs with the incidence of stunting toddlers.

MATERIALS AND METHODS

This research used observational analytic research with cross-sectional approach. The research was conducted in a village of Demak Regency for eight months from May - December 2019. The population in this study were 155 toddlers who were stunted. The sampling technique in this study was purposive sampling method. The inclusion criterion was minimum age of 2 years and a maximum of 5 years. Samples obtained were 100 respondents.

The instrument used in this study was questionnaires containing the child's identity, mother identity and 41 questions about fulfilment of the basic needs of children, which included 25 questions for physical, 10 questions for emotion, and six questions for stimulation. The independent variable in this study was the fulfilment of the basic needs of children and the dependent variable was stunting. This study received ethical approval from Medical/Health Research from the Commission of the Faculty of Medicine in UNISSULA with No. 642 / X / 2019 / Bioethics Commission.

RESULTS

Based on Table 1, it can be seen that 63.0% of respondents are included in the high-risk age category, 81.0% have basic education, 51.0% are housewives, 92.0% earn below the minimum wage payment, 60.0% are male, 50.0% were in short status and 50.0% were very short.

The results of the study (Table 2) found that 70.0% of respondents in the low risk category had toddlers with a short status and 56.0% were very short, respondents with basic education 80.0% had short toddlers and 82.0% were very short, Respondents as housewives, 50.0% had short toddlers and 52.0% were very short; income less than MWP, 90.0% had short toddlers and 94.0% were very short while for gender of stunting in toddlers 54.0% are short and 66.0% are very short occurring in boys under five. The characteristics of respondents had no significant relationship with stunting in toddlers (p value> 0.05), but there was a significant relationship between fulfilment of the basic needs, including physical, emotion and stimulation with the incidence of stunting in toddlers (p value 0.000 < .05).

DISCUSSION

The fulfilment of the basic needs of physical and emotion affects the condition of toddlers with stunting. According to the director of the budget in the field of human and cultural development in 2018, stunting is caused by multidimensional factors including bad child care practices, meaning children aged 0-6 months are not getting exclusive breastfeeding and children aged> 6-24 months do not get the appropriate complementary feeding, while children aged 3-6 years old are not registered in an early childhood education programme, show decreased level of attendance in Integrated Healthcare Centres, and do not get adequate access to immunisation services (Direktur Anggaran Bidang Pembangunan Manusia dan Kebudayaan, 2018). The results showed that for toddlers with both short and very short status, neither physical nor emotional needs were met. Based on the questionnaire, it is known that the majority of infants do not get breastfeeding and have complementary feeding before the age of 6 months. The complementary feeding given is not suitable for the baby's age, whereas in children aged 12 - 60 months the feeding does not meet balanced nutrition. This includes bad parenting and child care needs not being met. This is in line with the research of Rahmayana, Ibrahim, and Darmayati (2014) which stated there was a significant relationship between feeding practices with stunting in toddlers. Feeding infants and children is an important foundation in the growth process. Globally, around 30% of children under five years who are stunted are a consequence of poor feeding practices and recurrent infections (Rahmayana et al., 2014).

Maternal nutrition knowledge in Mimika Regency was found to be 80% of respondents in good category and 20% in less category. The level of maternal education also determines the convenience of mothers in absorbing and understanding the nutritional knowledge gained. This can be the basis for distinguishing the appropriate extension methods. From the family's nutritional importance,

education is needed so that a person, especially mothers, is more responsive to the nutritional problems in the family and can take action as soon as possible. High maternal knowledge is able to provide a balanced nutritional intake for families and children. Higher maternal knowledge is more prevalent in well-educated mothers than in poorly educated mothers. Good maternal nutritional knowledge does not always mean a child experiences

optimal growth; in cases where the mother is well-knowledgeable ,m17.5% of children have stunting (Silas, Rantetampang, Tingginehe, & Mallongi, 2018).

The association between education, in general, and health education in particular, with the level of stunting even after controlling for other socioeconomic factors underlines the need for customised health/nutrition education to make it more relevant to the existing situation and

underscores the need to fulfil the right to education. Importantly, children born of young mothers are at increased risk for stunting as these age groups are more active and involved in various income generating activities while the age of their children reflects a period of high risk. Similarly, the children from households having no access to irrigation and livestock are likely to be at a higher risk of stunting. This substantiates the longstanding fact that livestock and irrigation are critical components of food security in this community. The findings suggest that children from households that practise inappropriate child eating habits and food taboos are at increased risk for underweight and wasting. This complements the results of a pocket study in the country (unpublished), which found that children from households practising the old age traditional feeding habits are twice as likely to be malnourished. This finding underscores the importance of feeding the child separately and confirms its usefulness in avoiding the risk of child malnutrition. In terms of the right to nutrition security, 44.5% of the children exposed by the study were found as having chronic malnutrition. This is a type of malnutrition that reflects an extended period of deprivation. The study also captured violations of a short-term nature which affected 9% of the children as depicted by prevalence of wasting. The need to have an enabling environment in which individuals can provide for their own and their families' needs are stressed in the voluntary guidelines that provide a rich and very detailed set of recommendations and an agenda for action for the progress to realisation of the right to food (Hidar & Abate, 2005).

Emotional needs are children's need for the development of love, spirituality, independence, security, comfort, and sense of belonging. Emotional needs can provide a sense of security if physical and psychological contact is fulfilled as early as possible by the mother (Soetjiningsih, 2013). One of the needs that can be done immediately after birth is for the mother to hold the baby (skin to skin contact). The results showed that there was a significant relationship between fulfilment of the needs of caring for the incidence of stunted toddlers; based on a questionnaire given to respondents, there were things related to the success of breastfeeding, namely the question of early breastfeeding initiation. Eighty per cent of respondents stated that when giving birth to a baby they were not immediately held to the breast of the mother or had no early breastfeeding experience. Early initiation is the beginning of breastfeeding activities within the first hour after the baby is born. Early initiation can also be interpreted

as a way for babies to breastfeed the first hour after birth with their own efforts, in other words selfbreastfeeding instead of being breastfed. The way the baby initiates breastfeeding early is called the Breast Crawl or crawl looking for breasts. One of the benefits of IMD is that the baby is more successful at breastfeeding exclusively and will be breastfed longer (Roesli, 2008). One of the factors causing stunting is that the baby does not get exclusive breastfeeding (Kemenkes, 2018). This is in line with (Mawaddah, 2018) who states that there is a relationship between the EBM (Early Breastfeeding Initialization) variable exclusive breastfeeding. The Odd Ratio 9.17 (95% CI) shows that respondents who were not given breastfeeding initiation were 9.17 times more at risk of not getting exclusive breastfeeding compared with respondents who were initiated into breastfeeding (Mawaddah, 2018).

Stimulation needs are very important to support the growth and development of children. The more often the child gets stimulation, their development is faster than children who get little stimulation. During pregnancy, stimulation can be done from when the child is in the womb and after the child is born by giving breastmilk as early as possible. The child also needs stimulation as early as possible to develop motor skills, sensory awareness, social-emotional skills, language, cognitive processes, independence, creativity and leadership, and become moral and spiritual children (Kemenke, 2018). Based on the questionnaire, 88% of respondents did not provide stimulation to children. Stimulation is stimulus that is carried out from newborn (even preferably when in the womb) and is carried out every day to stimulate all the sensory systems (hearing, vision, touch, smell, smell). In addition, it must also stimulate rough and smooth motion of feet, hands and fingers, invite communication, and stimulate feelings that delight babies and children. Stimulation is important in children's growth and development. The results showed that children who lack of love and lack of stimulation will experience obstacles in their growth and development as well as difficulties in interacting with others. Stimulation given to children during the first three years (golden age) will provide an enormous influence on the development of the brain and become the basis for forming life to come (Setiawan, 2019).

CONCLUSION

Age, education, occupation and family income do not influence the occurrence of stunting in under five children, while the pattern of the fulfilment of the basic needs, which includes exclusive breastfeeding,

complementary feeding, emotional needs (early breastfeeding initiation and early stimulation) have a significant relationship with the incidence of stunting in toddlers.

Modern and Classic Wound Dressing Comparison in Wound Healing, Comfort and

Ferdiansyah Mahyudin, Mouli Edward, M. Hardian Basuki, Yunus Basrewan, and Ansari Rahman

Orthopaedic and Traumatology Department, Faculty of Medicine, Universitas Airlangga - RSUD Dr. Soetomo, Surabaya, East Java, Indonesia

ABSTRACT

Introduction: Wound care has also developed rapidly after the dissemination of the concept of TIME (Tissue, Infection, Moisture, and Wound Edge) in modern dressing (MD). The aim of this study was to compare modern dressings (MDs) and classic dressings (CDs) in terms of patient comfort, cost effectiveness and wound healing.

Methods: A prospective study design with total of 25 participants. The sampling technique used was consecutive sampling. Patient comfort was assessed through the frequency of wound care and pain scale using the Visual Analogue Scale (VAS). Cost-effectiveness was assessed using direct and indirect costs. Wound healing was assessed using the Bates-Jensen Wound Assessment Tool (BWAT) score. The data was analyzed using the independent t and Mann-Whitney tests.

Results: In terms of comfort, the mean for the number of times that wound care was performed and the pain scale in the participants using MD was (3.07 \pm 0.88 times and VAS 4.59 \pm 0.72, respectively), which is less compared to using CD (4.60 \pm 1.84 times each and VAS 5.43 \pm 0.75). Referring to the indirect and direct costs, MD (13.67 \pm 6.09 and 527.63 \pm 84.47, respectively) has the same cost-effectiveness as CD (14.00 \pm 7.64 and 482.68 \pm 98.08, respectively). In terms of healing, the mean of the BWAT score in MD (31.26 \pm 1.69) was better compared to CD (33.07 \pm 1.65).

Conclusion: The application of MD has the same cost-effectiveness as CD with a more satisfactory outcome for the wounds in terms of comfort and healing.

INTRODUCTION

A wound is a disorder of the normal condition of the skin in the form of damage to its continuity due to a pathological process, be it internal or external. Wounds often occur in daily life and they can lead to serious complications if not treated adequately (Gonzalez, Andrade, Costa, & Medrado, 2016).

The incidence of wounds is increasing annually. More than 1.2 million people have died globally due to traffic accidents and between 20-50 million people have suffered non-fatal injuries, including wounds. Most injuries, both acute and chronic in the global population, are caused by trauma (48.00%), foot ulcers (28.00%) and pressure sores (21.00%). Acute

wounds occur with a rapid onset and the healing process can be estimated. For example, injuries due to trauma or surgery. The healing process for chronic wounds cannot be predicted, for example, as in pressure ulcers, injuries due to malignancy and others (Gurtner, 2007). In developing countries, 1-2% of the population is predicted to have suffered from a chronic injury during their lifetime (Hurley, Knepper, & Price, 2013).

In Indonesia, the incidence of injuries is quite high along with the increasing incidence of traffic accidents in recent decades. In Surabaya, particularly at the Dr. Soetomo Regional General Hospital in Surabaya, 147 orthopedic patients with injuries were treated in the Acute Surgical Treatment Room between January 2016 and March 2017. There was a male to female ratio of four to one; 90% of them were injuries due to trauma.

Both acute and chronic wounds require good wound care and management. Wound management is an act of wound care that includes all elements including comorbid control and complications that can result from an injury. The series of activities include cleaning the wound and changing the dressing. The conventional wound care that is often done using tulle and gauze requires a long healing time, especially for chronic wounds with certain complications. Long days of care and visits conducted by the medical personnel that need to be more frequent will have an impact on the cost of care. In addition, in terms of comfort, patients treated using conventional bandages often complain of pain when dressing because the wound tends to adhere with the dressing (Morrison, Moffatt, & Franks, 2007).

In the last two decades, wound care has experienced rapid developments. Developments in the field of wound care began knowledge of the TIME concept (Tissue, Infection, Moisture, and Wound Edge) was been applied to the MD that is widely circulating today. MDs are a product of high-tech wound dressing. This type of dressing is able to control the humidity around the wound. A humid atmosphere will help to provide the atmosphere needed for there to be a local defense made by macrophages, accelerating angiogenesis and thus accelerating the wound healing process. In addition, it is expected that the use of MD can further increase the cost effectiveness and comfort of the patients (Daunton, Kothari, Smith, & Steele, 2012).

The application of wound care methods through the MD route in Indonesia is still relatively small. This is because the majority of health care facilities tend to use CD. The aim of this study was to compare modern dressings (MDs) and classic dressings (CDs) in terms of patient comfort, cost effectiveness and wound healing.

MATERIALS AND METHODS

This was a clinical observational study conducted using a prospective design approach in order to compare the outcome of wound care between MD and CD. The research subjects were orthopedic and traumatology patients with wounds treated in the surgical ward of Dr. Soetomo Regional General Hospital in Surabaya between March 2018 and February 2019. The inclusion criteria consisted of acute wounds caused by trauma where the raw surface of the wounds was 50-500 cm2 and where the depth of the wound ranged from partial to full thickness with skin loss down to muscle level. The exclusion criteria in this study included wounds with a raw surfaces of less than 50 cm2 or more than 500 cm2, wounds that are without an exposure of bone, tendon, nerve, vascular and cartilage and wounds in patients with multiple traumas or with comorbidities

like anemia, hypoalbuminemia or systemic diseases such as diabetes mellitus or malignancy.

The dependent variable in this study is the type of dressing (MD and CD) while the independent variables are (1) patient comfort assessed by how often wound care was performed and the pain scale each time that wound care was performed, (2) cost effectiveness as seen from the direct and indirect costs and (3) wound healing. Wound care was carried out by the orthopedic resident based on the standard operational procedures for wound care in the hospital of Surabaya Province. First, hand scrubbing was conducted. An explanation of the procedure of wound care was given to the patient, followed by patient identification. The use of gloves was emphasized. The wound dressing was removed with tweezers and disposed of. The wound was cleaned with gauze and NaCl 0.9% from the inside out. The condition of the wound was noted and documented. The wound was closed with a primary dressing, followed by a secondary dressing. The dirty gauze was disposed of and the tweezers were cleaned in a 0.5% chlorine solution.

MD is a type of wound dressing that consists of CutimedSiltec® and CutimedSorbact®. This is a standard modern dressing in the hospital. CD is a type of wound dressing that consists of gauze and tulle. Patient comfort was assessed according to the frequency of wound care being performed until the wound was ready for definitive therapy with a soft tissue coverage procedure. The pain scale each time wound care was performed was assessed by VAS. VAS is a pain rating scale with points along the length of a 10-cm line that represents a continuum between "no pain" at the left end (0 cm) of the scale and the "worst pain" at the right end of the scale (10 cm) (Bechert & Abraham, 2009; Delgado et al., 2018). Cost effectiveness was assessed through the direct costs referring to the costs directly related to wound care including wound dressing materials, the use of pain medication during wound care, the use of antibiotic drugs due to complications from infected wounds and the hospital costs. Cost effectiveness was also assessed using indirect costs, referring to costs that are not directly related to the treatment process, including productivity problems, as well as the costs incurred by the patient's carer during their stay in hospital. This is directly proportional to their length of stay (LOS) (Al-Gharibi, Sharstha, & Al-Faras, 2018). Wound healing refers to where the wound condition was assessed using the BWAT score (see Table 3) every time that wound care was performed (Bates-Jensen, McCreath, Harputlu, & Patlan, 2019).

All of the data was tested for normality distribution using the Kolmogorov Smirnov test. Variant homogeneity was determined using the Levene test. The data that was normally distributed with homogeneous variants was compared using an independent T-test while the data that was not normally distributed with non-homogeneous variants was compared using the Mann-Whitney test.

This research has been approved by the Commission of Health Research Ethics Faculty of Dr. Soetomo General Hospital Surabaya no. 52/Panke.KKE/II/2018 on 13th February 2018.

RESULTS

The results of this study have been presented in tables and diagrams. The patients with wounds treated using MD totaled 13 men and 2 women. The patients with wounds treated using CD amounted to 6 men and 4 women. Patients with wounds treated using MD consisted of 6 people aged less than 30 years old, 5 people aged 30 to 50 years old and 4 people aged over 50 years old. Patients with wounds treated using CD consisted of 4 people aged less than 30 years old, 4 people aged 30 to 50 years old and 2 people aged more than 50 years old. Seven patients treated using MD suffered from upper extremity wounds and 8 patients suffered from lower extremity wounds. The patients with wounds treated using CD consisted of 1 person suffering from a wound in the upper extremities and 9 people suffering from wounds in the lower extremities. The complete data of these patients has been described in Table 1.

Based on Table 2, the area of the wounds in patients treated with MD was 233.13 \pm 91.97, the same as the area of the wounds treated with CD:170.60 \pm 117.01 (p > 0.05). The mean number of times that wound care performed in patients using MD (3.07 \pm 0.88) was less than the wound care frequency for patients using CD (4.60 \pm 1.84). There was a significant difference (p < 0.05). The initial VAS in patients treated with MD was 7.27 ± 0.96 , which is the same as the initial VAS in patients treated with CD of 7.40 \pm 0.84 (p > 0.05). The last VAS in patients using MD (2.60 \pm 0.63) was less than the last VAS in patients using CD (3.90 \pm 0.74); there were significant differences (p < 0.05). Likewise, the mean VAS in patients using MD (4.59 \pm 0.72) was less than the mean VAS in patients using CD (5.43 \pm 0.75); there were significant differences (p < 0.05). The duration of the wound stated to improve in patients treated with MD was 13.67 ± 6.09 days, which is slightly faster than the wound care performed for the patients treated with CD after 14.00 ± 7.64 days. There was no significant difference (p > 0.05). Similarly, referring to the direct cost for the patients treated with MD (527.63 \pm 84.47), it was slightly higher than for CD (482.68 ± 98.08) but not significantly different (p > 0.05). The initial BWAT score for patients treated with MD was 35.07 \pm 2.12, which is the same as the initial BWAT score for patients treated with CD, which was 35.00 ± 1.70 (p > 0.05). The last BWAT score in patients using MD (27.60 \pm 2.06) was better than the last BWAT score of the patients using CD (30.70 \pm 2.36); there was a significant difference (p < 0.05). Likewise, the mean BWAT score in patients using MD (31.26 ± 1.69) was better than the average BWAT score of patients using CD (33.07 \pm 1.65); there was a significant difference (p < 0.05).

DISCUSSION

According to the demographic data, most of the causes of injuries were traffic accidents. It was found that the majority of patients were male (76%) and the rest were female (24%). Among the patients who used MD, 87% of them were male and 13% were female. Regarding the patients who used CD, 60% were male and 40% were female. These results are consistent with other studies where men are the more common accident victims compared to women with a ratio of 3.2: 1 (Laiou et al., 2016). This relates to the proportion of road users being mostly male and the characteristics and attitudes of male motorists during traffic (Nastiti, 2017).

Based on age, it was found that the majority of patients were younger than 30 years old (40%). The patients aged 30-50 years totaled 36% and those over 50 years totaled 24%. In the patients using MD, it was found that the majority of patients were under the age of 30 years (40%), the patients aged 30-50 years totaled 33% and those over 50 years old totaled 27%. In the patients using CD, it was found that the patients under 30 years old totaled 40%, the patients aged 30-50 years totaled 40% and those over 50 years totaled 20%. The traffic accidents predominantly involved motorcycle riders with an average age of 15-29 years

Table 2. Comparison of Modern and Classic Dressings in Terms of Patient Comfort, Cost Effectiveness and Wound Healing

Pa	arameter	MD (n=15)	CD (n=10)	р
Wide of wounds		233.13 ± 91.97	170.60 ± 117.01	0.055 ^u

t = independent T-test

old, which is within the productive age range (Nastiti, 2017). Teenagers and young adults, especially from among the male population, were most at risk of traffic accidents, with the prevalence rates ranging from 11.1 to 42.6% for the 20-30 years old age group and from 4.6 to 97.2% for male subjects overall (Khatib, Gaidhane, Quazi, & Khatib, 2015).

In terms of patient comfort, the indicators were assessed included frequency of wound care being done and the pain scale during the wound care procedure being performed. In this study, the frequency of wound care performed on patients using CD was more often when compared to the wound care when done using CD. In addition, the pain scale experienced by patients treated with MD and CD was also different, where the patients who used MD tended to find it less painful than those who used CD. Wound care is an action used to achieve wound healing which involves different emotional aspects for each individual who experiences it, including pain. The more frequently that wound care is done, the more likely it is that the patient feels uncomfortable. It is undeniable that pain can affect wound care procedures. Pain that is not treated adequately can have a negative impact on wound healing and the quality of life of the patients. In a multinational study conducted by the European Wound Management Association (EWMA), clinicians assessed that the time to change the dressings when wound care is performed is where pain is felt most severely (Moffatt, Franks, & Hollingworth, 2004). Pain during wound care (procedural pain) is closely related to the type of dressing used and this can be assessed using VAS. The selection of a type of dressing that does not adhere to the wound base and that can be easily removed will be very helpful in terms of reducing patient pain (S Calne, Day, & Pediani, 2004; Granick, Sood, & Tomaselli, 2014). Gauze is most likely to cause pain because it tends to be more adherent to the wound base and Siltec is a type of silicone dressing that is more easily released when changing dressings. According to Morris (2009), based on his research on burns in pediatric patients, the use of silicone dressings can minimize the incidence of trauma and pain in most patients who are the subject of his research (Morris, 2009).

In terms of cost effectiveness, especially indirect costs, it can be seen from the duration of the wound that it is good to do the soft tissue coverage procedure. This measurement can also be based on the Length of Stay / LOS. In this study, the indirect cost of using CD was the same as the wound care for patients using MD, which was in parallel to direct cost. In other words, the costs incurred in the use of both types of dressings for wound care were not much different. According to Hutchinson (1990), the use of gauze for wound care is indeed cheaper but its duration for subsequent dressing changes is too short. This risks increasing the occurrence of infection in the wound (Hutchinson & McGuckin, 1990).

Furthermore, when viewed in terms of wound healing, the BWAT score can give us an idea of the wound condition of each patient when first treated until the end when the wounds are declared to be ready for the soft tissue coverage procedure (Greatrex-White & Moxey, 2015; Sussman & Bates-Jensen, 2007). The initial BWAT score for each wound, whether treated using CD or MD, showed no significant difference. By comparing the last BWAT score and the average BWAT score of the wounds treated using MD and CD, different scores were obtained. The last BWAT score and the mean show better and significant healing for the wounds treated using MD (see Figures 1 and 2). CutimedSorbact was used as a primary wound dressing because its active material in the form of dialkylcarbomyl chloride (DACC) is able to bind bacteria and other microorganisms from contaminated wounds. The active material has strong hydrophobic properties that are used to bind microorganisms that have cell surface hydrophobicity (CSH) quickly and effectively. This includes gram-positive bacteria such as S.aureus, Methicillin-Resistant Staphylococcus aureus (MRSA), Streptococci, gram-negative bacteria such as E.coli, Clostridium difficileand P.aeruginosa, and types of fungi such as C.albicans (Cutting & McGuire, 2015). As stated by Ljungh et al (2006), hydrophobic dressings should be used for wounds with exudates to bind microorganisms that express CSH Yanagisawa, & Wadstrom, 2006). In addition, Cooper and Jenkins (2016) reported the efficacy of DACC on CutimedSorbact concerning binding the biofilms formed by pathogens MRSA and P.aeruginosa (Cooper & Jenkins, 2016). As a secondary dressing, CutimedSiltec was used in this study because of its nature as an absorbent of silicon. This is very useful for absorbing any excess exudate in the wound. This is consistent with the research conducted by Rook et al (2019) which states that silicone dressings (a type of modern dressing material) have the ability to reduce exudates, to provide a moist wound environment for optimal healing, to keep the tissue around the wound healthy, to avoid maceration, and to minimize pain (Boateng, Matthews, Stevens, & Eccleston, 2008; Rook, Davies, Frenthoff, & Wurfel, 2019). The use of CutimedSiltec with material from silicone foam is instrumental to deliver water vapor and oxygen, in addition to providing thermal insulation to the wound bed. Its main advantage is its ability to accommodate exudates and is able to protect healthy tissue around the wound, because the material is highly absorbent and able to spread the exudate evenly throughout the absorbent layer and prevent leakage with semi-permeable material on the back (Jones, Grey, & Harding, 2006; Vermeulen H, Ubbink D, Goossens A, de Vos R, & Legemate D, 2005).

CONCLUSION

In terms of patient comfort, including the frequency of wound care and the pain scale during wound care, modern dressings have advantages over classic dressings. Based on the comparison of the indirect and direct costs, modern dressings have the same cost effectiveness as classic dressings. In terms of wound healing using the BWAT score, modern dressings have better efficacy compared to classic dressings.

Social Care in Improving Self-Concept of Leprosy Patients

Nur Hamim¹, Mariani Mariani¹, and Sismulyanto Sismulyanto²

¹Sekolah Tinggi Ilmu Kesehatan Hafshawaty Zainul Hasan, Probolinggo, East Java, Indonesia ²Sekolah Tinggi Ilmu Kesehatan Qomarul Huda Mataram, West Nusa Tenggara, Indonesia

ABSTRACT

Introduction: Many infectious diseases occur in developing countries with low socioeconomic conditions. One such is leprosy. Leprosy is common in developing countries as a result of the country's limited ability to provide adequate services, including among some health workers. Such health workers are lacking knowledge and understanding of the false beliefs of leprosy and its resulting disabilities. The purpose of this research is to formulate a social care model in improving self-concept of leprosy patients in Probolinggo District.

Methods: This research used explanatory research survey method with a cross-sectional approach. The sample was 56 respondents. The variables were family support, social care and self-concept. The data were collected using a questionnaire modelled on Liandi, Richard H's concept and The Tennessee Self-Concept Scale. The data were then analyzed by Partial Least Squares (PLS) to test the hypothesis and form the empirical model.

Results: The results showed social care was able to improve the self-concept of leprosy patients (T=5.800, T>1.96).

Conclusion: Therefore, it is expected that nurses continuously synergize in maintaining social care conditions with the community in order to improve the self-concept of leprosy patients.

INTRODUCTION

Infectious diseases are common in developing countries with low socioeconomic conditions. One such is leprosy (Montaya, 2010). Leprosy is common in developing countries as a result of the country's limited ability to provide adequate services in the areas of health, education, and socioeconomic welfare in the community; leprosy is still feared by the community, among families, and even including some health workers (Lucinda, 2014). The World Health Organization (WHO) (2013) indicates that Indonesia has 17,012 cases of leprosy, although its leprosy prevention is better, as indicated by being ranked 4th after India, Brazil and Nepal. As of December 2015, in the preceding ten years, Indonesia succeeded in reducing leprosy morbidity by 85% from 107,271 people to 17,012 people (WHO, 2013). From these data, East Java is the province with the most leprosy patients, with the number of patients reaching 4,293 cases, with patients who have a lifelong disability as

many as 184 and, childhood sufferers as many as 117 in the region of Madura, Tapal Kuda and Pantura (Ministry Of Helath (MOH), 2015). The case of leprosy patients in Probolinggo regency ranks seventh after Tuban, while the first order is Sampang Regency (Ministry Of Helath (MOH), 2015). Leprosy patients will experience body image or present their individual self-image. Illness and serious injury can damage self-concept, including disability. Adapting the behavior of illness can affect a person's feelings about their identity (Hobfolf, 2006). Threats to body image as well as self-esteem are often accompanied by feelings of shame, inadequacy and guilt. In a healthcare setting, people sometimes have to adjust to a situation that threatens their self-esteem, (Hasselhorn, 2010) and leprosy patients will experience some problems, both physically, psychologically, socially, and economically (Misch, 2010). A preliminary survey conducted in February 2016 from medical records at Glagah Puskesmas

Role	9	16	23	41	24	43	56	100	

Probolinggo District showed that there were 34 patients recorded from 2012 to 2015 and that most of the patients (41.03%) had experienced disability of Busier Pausi (PB), while those with disability level of Multi Basiler (MB) was as much as 58.97%. From the results of field observations with the help of health cadres from Glagah Puskesmas, researchers found that leprosy patients feel their self-esteem (selfconcept) is very low. Patients isolate themselves from society, even families. The main goal is for patients to socialize to the community to improve their selfconcept through s social approach. Social care in the provision of health services needs to be done (Curtis, van der Heijden, Kümmerlin, van Dam, & van der Schoot, 2009) so that, hopefully, the family is not just resigned to the state of patients who also isolate themselves from the family. Thus the nurse must also attend the family and patient to provide health education. The purpose of this research is to formulate a social care model in improving the selfconcept of leprosy patients.

MATERIALS AND METHODS

This research used explanatory research survey method with a cross-sectional approch. The sample was 56 respondents. The variables in this study were family support, social care and self-concept. The data were collected by three kinds of instruments. The family support was measured questionnaireadopted from Liandi (2011). The social care using questionnaires whas developed by researchers based on Richard H's concept (2015). The Tennessee Self-Concept Scale (Fitts, 1965) was used for measuring self-concept. The analysis technique used is a model based on variance or componentbased, known as Partial Least Squares (PLS). PLS is a powerful analysis, since it does not assume that data should be of a certain scale, can work with a small sample, and can also be used to confirm the theory (Ghozali, 2009). This study was approved by the Hafshawaty Pesantren Zainul Hasan Institute of

Table 5. Values of Outer Weights in Outer Model of Self-Concept of Leprosy Patients

Variable	Original sample	Sample mean	Standard Deviation	T statistic	P value	Information
	(0)	(M)	(STDEV)			
Empathy	0.999	0.897	0.115	8.697	0.000	Significant
Encouragement	0.086	0.085	0.294	0.295	0.769	Not significant
Facilitative	-0.164	-0.162	0.206	0.799	0.425	Not significant
Opportunity	0.519	0.520	0.108	4.800	0.000	Significant
Freedom	0.323	0.299	0.101	3.205	0.001	Significant
Attention	0.338	0.338	0.095	3.572	0.000	Significant
Participation	0.371	0.361	0.094	3.937	0.000	Significant
Self-image	0.416	0.406	0.079	5.238	0.000	Significant
Self-esteem	0.293	0.277	0.068	4.312	0.000	Significant
Self-role	-0.090	-0.083	0.093	0.964	0.336	Not significant
Personal Identity	0.542	0.518	0.076	7.108	0.000	Significant
Self-ideal	0.136	0.120	0.122	1.115	0.266	Not significant

Table 6. T-Statistic Value on Inner Model of Self- Concept of Leprosy Patients

Direct and Indirect Causality Relationships between exogenous and endogenous variables	Path parameter coefficient	Sample Mean (M)	Standard Dev	T- Statistic	P value	Information
The influence of <i>Family Support</i> (X1) on self-concept (Y1)	0.448	0.447	0.091	4.953	0.000	Significant
The influence of Family Support (X1) on Social care (X2)	0.344	0.393	0.087	3.960	0.000	Significant
The influence of <i>Social care</i> (X2) on <i>Self-concept</i> (Y1)	0.549	0.536	0.087	6.285	0.000	Significant

variables. Indicator of self-concept variable (self-role and self-ideal) was not significant (p value > 0.05), so the indicator must be discarded and only self- image, self-esteem and personal identity were significant and maintained in the model.

Inner model test result

Table 6 explains the path coefficient of paramaters based on PLS test. Individual reflective size is said to be valid if it has a loading correlation loading with the latent variable construct measured, ≥ 5%, or the Tstatistic value must be greater than 1,96 (two-party test) at the significance level $\alpha = 5\%$. Table 6 shows that family support influences the self-concept of leprosy patients (T=4.953), family support affects social care (T=3.960), and social care influences the self-concept of leprosy patients (T=6.285).

The self-concept model of leprosy patients is composed of three variables: family support, social care and self-concept. Self-concept in leprosy patients is directly affected by family support and social care. Self-care conditions of leprosy patients can be reinforced indirectly through social care channels reinforced by family support (Hamim, 2015). Based on the outer weights of the outer model test, there are several indicators of each latent variable that are not significant, so it must be reconstructed first to obtain the ideal model.

Based on Table 7, the results of the reconstruction of the leprosy self-concept model developed from However, further research is needed, in particular longitudinal and experimental design, to determine the effectiveness of social support on self-care behavior in individuals with heart failure, as this review reveals most of the cross-sectional, correlational research limits the ability to infer causality (Lucinda, 2014).

Thus, the important role of family support is to change the mindset of lepers and other people to bring about the quality of a better work life. These conditions will cause the desire of the patient to socialize with the surrounding environment and includes activities that exist within each household, . This is directed to improve working life conditions, which can raise the spirit of the sufferers in carrying out the task of achieving a normal life. Similarly, people around the patient will feel an integral part of their everyday life.

The influence of family support on social care

The condition of the influence of family support on social care has T-statistics of 3.977 (T > 1.96). Thus, there is influence of family support to social care. The condition of good support will have an impact on good culture so that the patient's activity can be improved maximally; the nurse will also benefit from the positive activity. Therefore, all components in the society are expected to maintain the existing conditions so that society will continue to be part of

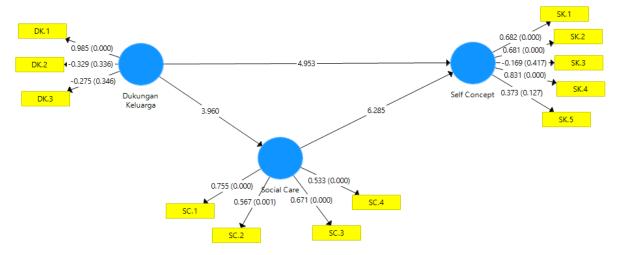

Figure 1. Self-concept model of leprosy patients based on path analysis before reconstruction

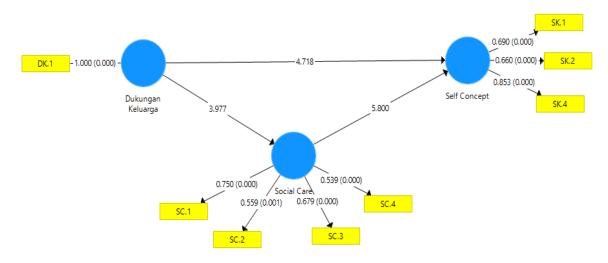

Figure 2. Test result model after reconstruction

the initial conditions expected by the patient (Friedman, 2013).

Social services are divided into two groups. First is social services, which are very complicated and comprehensive and so difficult to determine identity (Curtis et al., 2009). These services include education, social assistance in the form of money by the government, medical care and public housing. The second is clear social service scope and its services, although these are always changing. This service can stand on its own, for example child welfare and family welfare, but it can also be a part of other institutions, such as social work in schools, medical social work, social work in public housing and social work in industry. Social service in the broad sense is any service intended to improve the social welfare of human, while, in the narrow sense, it is the service given to some people who are less fortunate (Desi, 2011). Thus, in a synergy, the better the support of the family will have an impact on the overall social attention, because how can social attention can be maximized if there is no support from the family on the patient.

The effect of social care on the self-concept of leprosy patients

The results showed the influence of social care on the self-concept of leprosy patients. Table shows the influence of social care on self-concept of leprosy patients with a T-statistics score of 5.800 (T > 1.96). There is influence of social care to self-concept of leprosy patients. The concept of self defines all ideas, thoughts, feelings, and beliefs that involve individual knowledge about self and affects the relationship with others (Stuart & Sundeen, 2006). Self-concept consists of self-image, self-esteem, role of self, selfidentity and self-ideal, while the factor that influences the formation and development of self-concept is age. Self-concept is formed along with increasing age whereby this difference is more related to development tasks. Education also influences selfconcept. A person with a high level of education improves his achievement. If his achievement increases, then his self-concept will change. Socioeconomic status affects the acceptance of others toward him. Family relationships of a person

Table 7. T-Statistic Value of Inner Model Self- Concept of Leprosy Patients After Reconstruction

Direct and Indirect Causality Relationships between exogenous and endogenous variables	Path parameter coefficient	Sample Mean	Standard Dev	T- Statistic	P value	Information
The influence of Family Support (X1) on Self-Concept (Y1)	0.441	0.433	0.093	4.718	0.000	Significant
The influence of <i>Family Support</i> (X1) on <i>Social Care</i> (X2)	0.344	0.363	0.086	3.977	0.000	Significant
The influence of <i>Social Care</i> (X2) on <i>Self-Concept</i> (Y1)	0.556	0.563	0.096	5.800	0.000	Significant

who has a close relationship with his or her family members will identify with others and want to develop the same personality pattern, if this is a same-sex character it will develop a self-concept worthy of his sex. Other people make us know ourselves by knowing others first. How another knows ourself will contribute to form self-concept. Individuals are accepted by others, respected and liked because of their condition and individuals will tend to be respectful and accept him. Conversely, when others always underestimate themselves, blame, and reject, they will tend to not like him.

CONCLUSION

There is influence of family support to the self concept of leprosy patients. The findings show the influence of family support on the self-concept of leprosy patients. The better the family support, the higher the self-concept of leprosy patients. There is influence of family support to social care. From the results of analysis, it shows the influence of family support to social care, The better the family support, the better the social attention of society to leprosy patients. There is influence of social care to selfconcept of leprosy patients. Results analysis shows an influence of social care on self-concept of leprosy patients; the better social care or social attention of people to leprosy patients, the higher the self-concept of leprosy patients.

The Risk of Mortality on Patients with Traffic Accidents of Emergency Department at dr. Soebandi Regional Hospital, Jember Regency

Baskoro Setioputro, Indah Listiyawati, Kholid Rosyidi Muhammad Nur

Jember University, East Java, Indonesia

ABSTRACT

Introduction: The number of deaths due to traffic accidents has become a global burden. In addition SDGs 2030 has set a target to decrease the number of fatalities and global injuries due to traffic accidents. The purpose of this study was to analyse the risk of mortality due to traffic accidents in the Emergency Department (ED) of dr.Soebandi Hospital Regional, Jember Regency.

Methods: A retrospective observational study was carried out in the ED by studying medical records of the traffic accident patients aged ≥16 years. The sampling technique was simple random sampling with sample size 250. The study collected data with Modified Rapid Emergency Medicine Score. This study result was analyzed with frequency distribution and Chi-square test.

Results: The result showed respondents who experienced traffic accidents were mostly 20-29 years old (19.6%). The majority of the patients were men (68.4%). The riders of two/three-wheeled vehicles who suffered traffic accidents reached 73.2%. Most of the accidents occurred between 06.00-11.59am, 37.6%. Generally, traffic accidents occur to drivers as much as 68.4% and the number of types of head trauma as much as 57.2%. This study showed that 94.8% patients were at low risk of mortality. There was significant relationship between risk of mortality and the role in vehicle use (p-value = 0.043).

Conclusion: Almost all patients have a low risk of mortality in the ED of dr. Soebandi Hospital Jember Regency.

INTRODUCTION

Traffic accidents can increase mortality rates for vulnerable road users, such as bicycle riders, motor riders and pedestrians. Mortality rate due to traffic accidents is still a global burden and the 3.6th target of the Sustainable Development Goals 2030 program (SDGs) is to reduce half of global mortality and injury rates by 2020 (WHO, 2018; ILO, 2018). During the period 01 January to 30 December 2018, the number of traffic accidents in Indonesia reached 108,873 accidents with a total mortality of 25,511 people (National Traffic Police, 2019). One of the provinces contributing mortality rates due to traffic accidents is East Java. The number of traffic accidents in East Java during the period 01 April to 30 June 2019 reached 423 accidents with a total mortality of 104 victims (National Traffic Police, 2019). On the other hand, Jember Police data revealed that traffic accidents in

2018 reached 1,260 accidents with a total mortality of 379 victims (Wahyunik, 2019).

Traffic accidents can cause emergency condition for the victim (Ministry of Health of the Republic of Indonesia, 2016). Therefore it requires treatment within the first hour or what is often called as the golden period to save the victim (Korlantas Polri, 2019). One of the initial steps to save victims is determining risk of mortality in prioritizing victim care in health facilities. The Rapid Emergency Medicine Score (REMS) observation sheet can be used to determine patient's risk of mortality (Seak et al., 2017). Based on research by Nakhjavan-Shahraki, Bikpour, Youseifard, Nikhseresht, Razaz, Faridaalaee, and Hossein (2017), REMS can predict mortality events and adverse effects on patients in the **Emergency Department.**

However, REMS has a lower validity value than the Modified Rapid Emergency Medicine Score (mREMS) in determining the incidence of mortality in trauma patients. REMS validity value is 91.1% and 92.1% for mREMS. In addition, mREMS is suitable to apply in trauma cases. mREMS is better than some other trauma scores, such as the Mechanism of Glasgow Coma Scale and Arterial Pressure (MGAP), Revised Trauma Score (RTS), Injury Severity Score (ISS), Shock Index (ISS), and Shock Index SI). mREMS score range is between 0 and 26. Patients who have mREMS score 0 to 2 reached 70 mortalities (0.03%) out of 221,684 victims, while trauma patients having mREMS score 22 to 26 reached 1,781 mortality (91.2%) out of 1,952 victims. The higher the value of mREMS, the higher the mortality rate of patients with trauma (Miller et al., 2017).

The mREMS instrument consists of age, Systolic Blood Pressure (SBP), heart rate (HR), respiratory rate (RR), oxygen saturation, and Glasgow Coma Scale (GCS). These variables are needed by the EMS (Emergency Medical Service) officer or triage officer to check the patient's health status in making the decision to transport the victim to the most appropriate facility (Miller et al., 2017). Thus, it is important to know the score of the mREMS at the Hospital ED, which is the first emergency service.

Emergency services are expected to prevent the risk of disability and mortality in patients (to save life and limb) (Korlantas Polri, 2019). Emergency Departments experience an increase in the number of patient visits each year (Deviantony et al., 2017). Based on data from the dr. Soebandi Regional Hospital Emergency Department there were 2,402 patients with traffic accident in 2018. Therefore, it is important to know the patient's condition in preventing mortality, especially in the hospital emergency department. The assessment of mortality scores with mREMS is unknown in the dr. Soebandi Regional Hospital Emergency Department. This study aimed to analysis the risk of mortality patients with traffic accidents in the dr. Soebandi Regional Hospital Emergency Department, Jember Regency

MATERIALS AND METHODS

Quantitative research with retrospective approach was used in this study. Retrospective observational research is a research conducted on events that have occurred to see the risk factors of the causes of these events (Nursalam, 2015). This research was conducted for one month (December 2019-January 2020) using a variable risk level of patient mortality due to traffic accidents and the risk factors for mortality in the dr. Soebandi Regional Hospital, Emergency Department, Jember Regency. The population in this study is the data of medical records of patients with traffic accidents in the dr. Soebandi Regional Hospital, Emergency Department, Jember Regency in January to December 2018; there were 2,402 population while the number of samples used in the study was 250.

This study used probability sampling, which is a sampling technique by giving equal opportunities to each population to be selected as a sample (Sastroasmoro & Ismael, 2014). The technique in sampling used simple random sampling by randomization. This technique is a random sampling technique without considering strata in the population (Sugiyono, 2015). The instrument used in this study was the mREMS observation sheet. The mREMS component consists of age, SBP, HR, RR, SpO2 and GCS that are measured when the patient is in the first triage or during the primary survey. The AUC value of mREMS has been tested for validity and reliability by Miller, Nazir, McDonald and Cannon (2017) of 0.967 (95% CI (Confidence Interval): 0.963-0.971) which means that the validity level of mREMS is 96.7% to predict mortality of trauma patients in the hospital. mREMS had three categories in the risk of mortality: low risk (score 0-8), moderate risk (score 9-17), and high risk (18-26) (Miller et al., 2017).

This study employed univariate analysis of patient characteristics (such as age, education, gender, and occupation), season, day of traffic accident, time of traffic accident, type of road, role of patient using vehicle, type of trauma, patient information and level risk of mortality. The component is analyzed by percentage and frequency distribution. This study also employed bivariate analysis with Chi-square test. The Chi-square test was used for relationship between categorical variables with the risk of mortality (p<0.05). The research ethics were approved on October 21, 2019, by the ethics committee of the Faculty of Dentistry, University of Jember based on a certificate of ethical qualification number 594 / UN25.8 / KEPK / DL / 2019.

RESULTS

Respondent characteristic, risk factors, and risk of mortality of traffic accident patients were analyzed in this present study. Table 1 shows that the highest data of traffic accident patients characteristic in the dr. Soebandi Regional Hospital, Emergency Department, Jember Regency, in 2018 was age group of 20-29 years with 49 patients (19.6%), and 171 male patients (68.4%) with 94 high school education level patients (37.6%). Based on the type of employment often involved in crashes are farmers with 57 patients (22.8%). Table 1 shows that the characteristics of respondents' age, gender, education, and job had no significant relationship with risk of mortality.

Table 2 shows that, according to type of user, 2/3-wheeled motorized vehicles with about 183 patients (73.2%) became the highest case. Based on the distribution of the day, the highest accident occurrence was on Wednesday as many as 46 patients (18.4%) and Sunday as many as 40 respondents (16%), while based on the time of the incident there were 94 patients (37.6%) who had an accident at 06.00-11.59am. There were 134 respondents (54.0%) who had accidents in the dry season

dominated by drivers as many as 171 respondents (68.4%). The most types of trauma were head trauma of 143 respondents (57.2%) out of 250 respondents and referral patients were 158 respondents (63.2%). Table 2 found significant relationship in the role in vehicle use between risk of mortality (p = 0.043 < 0.05), but there wasn't a significant relationship in type of road, the day of occurrence, time of occurrence, season, type of trauma and patient information between the risk of mortality.

Table 3 illustrates the level of risk of mortality of patients due to traffic accidents in the dr. Soebandi Regional Hospital Emergency Department in Jember Regency that in 2018 there were 237 patients (94.8%) who had a low risk of mortality. The high risk of mortality is 12 patients (4.8%) and the lowest level risk of mortality is a high risk of one patient (0.4%)

DISCUSSION

This study analyzed 250 medical records from patients with traffic accident in the dr. Soebandi Regional Hospital, Emergency Department, Jember Regency. Most of the study samples or 237 patients (94.8%) had a low risk of mortality. Trauma patients death reached 6.0% with the highest proportion of head /spinal trauma patients (67%) (Eaton et al., 2017). In addition, other studies also showed 4.5% deaths in motorbike traffic accident, treated in ward (82.5%) and ICU (13%) (Fouda et al., 2016).

The high risk of mortality was caused by traffic accident. Traffic accidents can cause casualties to become an emergency (Ministry of Health of the Republic of Indonesia, 2016). An emergency case is a situation that can threaten a victim's life. Emergency case requires immediate treatment to reduce the

threat of life and an emergency situation needs to be handled quickly and appropriately to avoid the threat of life and disability in the limbs of the victim (Musliha, 2010). Thus, this requires treatment in the first hour, or what is often called the golden period, to

save the victim's condition (Kartikawati, 2012). There are trimodal mortality patterns in trauma. The first periode is the risk of mortality caused by disorders of the heart, large blood vessels, brain and spinal cord system. The second periode is is the risk of mortality

Table 3. Overview Risk of Mortality of Traffic Accident Patients (n = 250)

Mortality Risk	Frequency (n)	Percentage (%)
Low Risk	237	94.8
Moderate Risk	12	4.8
High Risk	1	0.4
Total	250	100

caused by intracranial bleeding, pelvic fracture and tears in solid organs bleeding. The third periode is the risk of mortality caused by sepsis, failure of some respiratory organs or other complications (American College Of Surgeons, 2018; Kartikawati, 2012; Sheehy, 2013).

This study showed one referral patient experienced the highest risk of mortality with an mREMS score 25. Patient had traffic accident between pedestrians and motorbikes on Sunday at 04.00am. The traffic accident was in early morning with vehicle tending to speeding because there are not many vehicles on the road. According to Rompis, Mallo, and Tomuka (2016), the slower the vehicle on the road, the higher the severity of the patient's condition due to traffic accidents. On the other hand, this 68-yearold patient was also diagnosed with brain hemorrhage and open fracture femur, systolic blood pressure (78mmHg), heart rate (39 x/min), respiratory rate (5x/min), SPO2 (74) %), and GCS (3). Hemorrhagic brain can increase intracranial pressure, which increases the risk of cerebral hypoxia (lack of oxygen), cerebral necrosis, cerebral ischemia, brain tissue edema, and brain herniation. Open fracture femurs can cause massive bleeding according to the location of the fracture and its trauma (Sheehy, 2013; Ulya et al., 2017). These conditions can increase patient's risk of mortality.

In addition to the types of trauma above, the patients' vital signs are in the abnormal range. According to Ha et al. (2017), the vital signs of patients experiencing the risk of mortality are patients with abnormal vital signs and as much as 5% risk of mortality with respiratory distress from the first eight hours to 48 hours. Systolic blood pressure, GCS, and RR also affect the risk of mortality. The lower the value of systolic blood pressure, GCS, and RR the higher risk of mortality (Ristanto et al., 2016). SBP (<90mmHg) can predict the risk of patient mortality (Liu et al., 2012). If the SpO2 is lower (<90%), it can increase the risk of mortality within 24 hours (Ha et al., 2017). Age also plays a role in determining the level of risk of mortality in trauma patients. Lingsma, Roozenbeek, Steyerberg, Murray, and Maas (2010), showed that the older the age of the patients, the worse their condition. This was caused by decreased neurological function and disability conditions increased.

The role in vehicle use has significant relationship with risk of mortality (p = 0.043). The role in vehicle use as drivers often experiences traffic accidents (68.4%). Drivers had the risk of mortality (67.8 %) due to traffic accident in Tomohon. This incident was caused by an undisciplined driver using a seat belt, on the motorist's helmet and completeness of the letter,

the condition of the driver who was tired, drunk (or the influence of alcohol and drugs) and / or sleepy (Rompis et al., 2016). Drivers had 66,2% experience of traffic accidents (Angela et al., 2013). Thus, researchers assume that drivers have higher risk of mortality due to traffic accidents.

The age group of 20-29 years often experiences traffic accidents (19.6%). Generally traffic accidents at Guilan Province Medical Center occur in the age group of 20-29 years (32.2%) (Amiri et al., 2016). Other studies show that ages 21-30 years dominate traffic accidents (33.46%) (Yogesh, 2015). So it can be seen that the productive age group and adult contribute in the occurrence of traffic accidents. This is because these age groups have anger and are less stable. As a result, there is lack level of caution and discipline in using vehicles and roads (Rompis et al., 2016). Researchers assume that traffic accidents often occur in the age group 21-29 years with status as students and workers due to the time when the accident happened; 6 am to 11.59am is the time where students go home and go to school. However, based on Chi-square test, there is no significant relationship between the age group and risk of mortality (P = 0.427).

Type of road user who frequently experience traffic accidents are 2-wheeled or 3-wheeled motor riders (73.2%). Motorcycle users often experience traffic accidents (53.78%) (Wicaksono et al, 2014). Another study explained that the number of motorcycle users who experienced traffic accidents was 65% (Herawati, 2014). This is due to an increase in the number of motorized vehicles, which in developing countries sees an increase occurred in two-wheeled motor vehicles and buses (Nugroho & Yulianti, 2016). On the other hand, drivers and passengers of motorized vehicles are not protected by security as are car drivers (Rompis et al., 2016). Researchers assume that two or three-wheeled motorized vehicle users have a vulnerability to traffic accidents due to lack of safety driving behavior. However, the Chi-square test showed no significant relationship between type of vehicle and the risk of mortality (p = 0.122 > 0.05).

Traffic accident patients at the ED of dr. Soebandi Regional Hospital, Jember Regency, in 2018 often occurred from 06.00-11.59am (morning) (37.6%). This research is in line with the results of Herawati's research (2014), stating that the highest number of traffic accidents occurred 06.00-12.00am and 12.00-18.00pmeach as much as 31%. Most traffic accidents occurred at 12.00-18.00pm (31.74%) (Wicaksono et al., 2014). Other research also explains that 12.00-18.00pmis a time that often occurs traffic accidents, by 44% (Saputra, 2017). This is because at 06.00-

11.59am and 12.00-17.59pmare the peak of outdoor activities, which means that people tend to go out at the same time, either for going to school or having lunch, so that the level of traffic accidents is greater (Rompis et al., 2016). Although traffic accident tends to increase in a specific time, there is no significant relationship between time of traffic accident and risk of mortality (Chi-square test p = 0.070 > 005).

Furthermore, the number of male patients in the ED of dr. Soebandi Regional Hospital due to traffic accidents reached 68.4%. But the gender does not have significant relationship with risk of mortality (p = 0.299 > 0.05). Male dominates the incident of traffic accidents by 88.5% (Katageri et al., 2015). The fatalities were primarily male (98.5%) (Kotwal et al., 2019). The ratio of injuries due to traffic accidents between men and women is 8.4: 1 (Hosseinpour et al., 2017). Furthermore, traffic accident victims who experienced mortality in the city of Tomohon for the 2012-2014 period were 84.75% men (84.75%) (Rompis et al., 2016). Gender which frequently experiences traffic accidents is men. Factors that cause an increase in traffic accidents in men are behavior patterns in driving, mobility levels, and male dominance on the road (Oktavianti, 2016; Rompis et

In this study, traffic accident patients experienced head trauma (57.2%), and lower limb trauma (40.0%). Lower extremities consist of femur, tibia, fibula, patella, tarsal, metatarsal, and phalanges (Ros & Wilson, 2014). Other studies also explained that head trauma due to traffic accidents reached 87.8% and external trauma as much as 92.8% (Nugroho& Yulianti, 2016). The type of trauma that usually occurs in traffic accident victims is extremity trauma as much as 28% (Yogesh et al., 2015). Generally, head and neck trauma is experienced by victims of traffic accidents by 26.4% (Amiri et al., 2016). Head trauma is caused due to negligence in the use of helmets. The use of helmets can reduce the incidence of severe head injuries by 70%. Traumatic injuries also often occur due to traffic accidents because of primary impact or secondary impact; secondary impact is caused by a collision with an opposing vehicle and / or highway (Oktavianti, 2016). The highest mortality rates occur in patients with chest trauma (22.2%) and head trauma (14.7%) (Fouda et al., 2016). This research result showed no significant relationship between type of trauma and risk of mortality (p = 0.689).

The limitation of this study was it only analyzed medical record patients in one year and only in one hospital. This study cannot show risk of mortality trend due to regulation change that makes patients go to first referral hospitals.

CONCLUSION

The conclusion of this research was that almost all patients with traffic accident in the ED dr.Soebandi regional hospital (94.8%) had low risk of mortality. Traffic accidents often occurred in the age group of 20

to 29 years (19.6%) and the male group (68.4%). Traffic accidents were often experienced by riders of 2 or 3-wheeled motor vehicles (73.2%), while the highest type of trauma in traffic accident patients was head trauma (41.7%). There was a significant relationship between the role in vehicle use with the risk of mortality. Future studies can focus on the prevention risk of mortality for patients due to traffic accidents according to role in vehicle use. The clinical implication of this research is a source of data for health workers to make clinical decisions at various levels risk of mortality for patients with traffic accidents. This is expected to prevent worsening in the patient's condition.

Family Health Tasks Implementation and Medication Adherence of Pulmonary Tuberculosis Patients: A Correlational Study

Tintin Sukartini, Nora Dwi Purwanti, and Herdina Mariyanti

Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Introduction: Non-adherence medication is found among patients with pulmonary tuberculosis. Various factors influence patient adherence to medication. The purpose of this study was to analyze the relationship between family health tasks to medication adherence among patients with pulmonary tuberculosis.

Methods: The design of this study was cross-sectional, with 45 sample size of pulmonary tuberculosis patients at Polyclinic of Pulmonary Disease in Haji General Hospital Surabaya taken by using a purposive sampling technique. Independent variables of this study were family health task which includes five dimensions, recognizing the family member health problem, making decisions for appropriate treatment measures, caring for sick family members, modifying the healthy environment and utilizing the healthcare facilities. The dependent variable was medication adherence. Data were taken using the questionnaires then analyzed by Spearman rho test.

Results: There was a relation between tasks of family health: recognizing the family member health problem (p=0.001), taking decisions for appropriate treatment measures (p=0.000), caring for sick family members (p=0.003), modifying the healthy environment (p=0.006), and utilizing the healthcare facilities (p=0.001) with medication adherence in patients with pulmonary tuberculosis.

Conclusion: The research of this study suggests the hospital arrange health education for the family and the patient to increase the quality of health services. The family can provide a conducive environment for the patient and further research can develop better research by using other methods such as direct observation, demonstration, and simulation.

INTRODUCTION

Non-adherence to medication was found as the cause of multidrug-resistant TB (MDR-TB). In 2013, the World Health Organization (WHO) declared MDR-TB as a worldwide crisis due to the number of new cases each year almost reached half a million and that cased continues to emerge with serious epidemics in some countries. Moreover, there were detected amount 136,000 cases eligible for MDR-TB treatment (WHO, 2014). The surveillance of TB prevalence in Indonesia reported positive tuberculosis smear amounted to 257 per 100,000 citizens with upper age 15 years old. The notification rate (CNR) in 2015 for all cases was 117 per 100,000 citizens (Ministry of Health Republic of Indonesia, 2016). The survey of tuberculosis

prevalence in 2014, Indonesia was noticed as the second largest contributor of tuberculosis patients after India. In 2015, the East Java Province of Indonesia reported new cases of positive smear amounted to 23,183 patients, which revealed a case detection rate of t 56%, whereas the target was 70% (East Java Provincial Health Office, 2016).

Pulmonary tuberculosis is one of the world's health problems, although control efforts with the Directly Observed Treatment, Short-course (DOTS) strategy have been implemented in many countries since 1995 (Kementerian Kesehatan (Kemenkes—MOH), 2014). One of the main challenges to pulmonary tuberculosis control in Indonesia is the presence of drug-resistance, especially Multidrug-resistant TB. TB resistance rates are currently low,

but the number of MDR-TB cases tends to increase every year (Deprtemen Kesehatan Republik Indonesia, 2013). The WHO also stated that, by 2013, the world was experiencing a crisis of MDR-TB (World Health Organization, 2015). One of the contributing factors to the increase in MDR-TB cases is the lack of patient adherence in TB treatment (Kementerian Kesehatan (Kemenkes—MOH), 2014).

Non-adherence of patients in taking anti-TB drugs can be caused due to several factors, such as length of treatment period that causes boredom or feeling of healed so that patients tend to stop treatment unilaterally before the treatment program is complete (Kementerian Kesehatan (Kemenkes-MOH), 2014). The patient's personal experience of side effects from anti-TB drugs also influences the patient's compliance with the drug. Another factor that causes noncompliance of TB patients in taking medication is due to inadequate oversight of the Supervisors of Swallowing Drugs (SSD). The SSD is the person closest to the patient, as well as the health officer who oversees the patient in taking the medicine. In this case, the family is thought to be more effective in the patient's drug supervision, as the family is the immediate neighborhood of the patient. The results of interviews with some pulmonary TB patients at Pulmonary poly, General Hospital Haji Surabaya stated that they received good support from their families so that they were willing to undergo a prescribed treatment procedure, but others said that, during suffering from tuberculosis, they felt the lack of good care of their family

Green and Kreuter's (2005) behavioral theory of mentions three factors that influence the health behavior of individuals, namely (1) predisposing factors are factors that exist in the individual self, such as knowledge, attitudes, values, beliefs and others; (2) the enabling factor is a supporting factor of the individual environment, which includes the availability of human resources, accessibility to human resources, community / government regulations, priorities and commitment to health and so on; (3) the reinforcing factor is a factor that reinforces the occurrence of health behavior, family support, peers, teachers, community stores and attitudes of health care providers (Green and Kreuter, 2005).

The factor in the formulation of medication behavior of pulmonary tuberculosis patients is the presence of family support, which can be evaluated through the implementation of family health tasks. The family has a health maintenance role, which includes five family health tasks: recognize health problems in the family, take decisions for appropriate treatment measures, care for sick family members, modify a healthy environment, as well as utilize the healthcare facilities that are available around the neighborhood to the maximum. The role of families in the implementation of family health tasks is needed in the treatment process. Personal family is the main factor of patient healing. The role of the family in motivating the patient to take the medicine,

explaining that the treatment is important, helping to get the medicine, to make the patient always take the medicine, give treatment and give the impetus to recover quickly (Risnawati, 2016) will form patient compliance during treatment procedures.

Family can be an influential factor in determining the beliefs and value of individual health and establishing a treatment program they can receive (Niven, 2012). A study conducted by (Pameswari, Halim and Yustika, 2016) states that the role of the family as an SSD is necessary. The role of an SSD is to improve patient compliance to take medication regularly and uninterruptedly, increasing the patient's willingness to control and re-check the sputum according to the time specified, encouraging to recover, assisting costs (finances) for treatment, encouraging patients to rest, provide nutritious food for patients, and clean the house and environment well. (Pameswari, Halim and Yustika, 2016) also explained that, based on the results of research, some respondents said the size of family support and always reminding to take medication on time were the main reason why they were obedient. The purpose of the study was to analyze the relationship between family health tasks to medication adherence among patients with pulmonary tuberculosis

MATERIALS AND METHODS

This research uses correlational design with the cross-sectional approach. The population in this study was patients and families of pulmonary tuberculosis at Polyclinic of Pulmonary Disease in Haji General Hospital Surabaya, in July-September 2016. The inclusion criteria of this study were TB patients under intensive and advance treatment by age 18 to 54 years old with in-house family members. Patients under treatment without family assistance, the family assistance member under 21 years old were included in the exclusion criteria. The sample was chosen by a purposive sampling technique based on inclusion and exclusion criteria which resulted in a large sample of 45 patients.

The independent variable in this research is a family health task consisting of five dimensions of family health tasks: recognizing the family member health problem, taking decisions for appropriate treatment measures, caring for sick family members, modifying healthy environment and utilizing the healthcare facilities. The dependent variable is medication adherence.

The data collecting process used the instrument to collect data from patients and family about patient and family demography, family task implementation in treating the family member with TB and patient adherence to taking medication. The instrument of family health task implementation contains 40 questions taken from research conducted by Marwansyah (2012) with modifications from other researches. Determination of answer was using Likert scale, with a score range of 1 – 4. The classification of questionnaire assessment results in this study are: 1)

the highest score is the highest value weighted by the number of questions, 2) the lowest value is the lowest value weight of the number of questions, 3) range is the highest number of values minus the number of lowest values then created intervals is the range divided by the number of categories. The criteria categories are divided into three based on the mean value and standard deviation of the questionnaire question scores: 1) good: X > mean + standard deviation, 2) enough: mean-standard deviation < x < mean + standard deviation, and 3) less: x < mean + standard deviation

Instrument for adherence to medications uses MMAS-8 (Morisky Medication Adherence Scale) that contains eight questions. This questionnaire was taken from The Journal of Clinical Hypertension (Okello et al., 2016). The questionnaire is most often used to measure compliance with the drug in hypertensive clients, but has been modified so that it can also be used to determine the level of compliance with some chronic diseases requiring long medication treatment (Morisky, Green and Levne, 1986). Determination of the answer was by using a Guttman scale, where the respondent's answer is only limited to the answer "Yes" which is given a score of 1 and "No" which is given a score of 0. The patient and family filled the questions during waiting time to control with a doctor or after treatment without interruption during treatment.

Researchers went through several phases during data collection, including requesting permission for the research activities, identification of research respondents, informed consent to research respondents willing to follow the research, replenishment of questionnaires accompanied by mentoring during the filling of questionnaires, and short interviews to selected research respondents. Data obtained were analyzed by using statistical test of Spearman Rho with degree of significance 0.05. The researcher obtained ethical permission from the Ethics Committee of the Faculty of Nursing, Universitas Airlangga, Surabaya, with number 270-KEPK.

RESULTS

The results showed that most of the TB patients were aged between 46-55 years old (24.4%), most of them female (55.6%), with the highest level of education (Senior High School) 46.7%. Most TB patients were unemployed (28.9%) and most were currently undergoing TB treatment in an advanced phase (60%). The result of the research showed that most of the family members' age was between 26-34 years old (33.3%), female (57.8%), with the highest level of education (Senior High School) 57.8% and the most jobs were entrepreneurs (31.1%) (Table 1).

The results showed that most families had performed general family health tasks in good category with frequency (62.2%). Family health tasks that have been well implemented are mostly caring for sick family members (66.7%), while family health

tasks that have not been well implemented are recognizing health problems in the family and modifying a healthy environment (Table 2).

From the results of the research in the table above can be concluded that the medication adherence for patients of pulmonary tuberculosis treatment in Pulmonary poly, General Hospital Haji Surabaya is mostly in high category, as many as 25 patients (55.6%). In the research results, there are still respondents who have low adherence level, as many as one respondent (2.2%) (Table 3).

Implementation of family health tasks in good category has high medication adherence category as many as 20 people (44.5%). In the research result, there are still families with the implementation of family health tasks in the enough category, but the level of medication adherence is low as many as one person (2.2%). The result of statistical analysis with Spearman Rho correlation test found that there is a relationship between the implementation of family health tasks with the medication adherence of TB patient. Implementation of family health task 'recognize the health problems of family members' in the good category has the highest level of medication adherence as many as 13 people (28.9%). In the research result, there are still families with family health task implementation 'recognize health problem of family members' in the less category, but having medication adherence level of moderate category as many as three people (6.6%). The results of statistical analysis with Spearman Rho correlation test obtained there is a relationship between the implementation of family health task 'recognize the health problems of family members' with medication of pulmonary tuberculosis patients. Implementation of family health task 'taking decisions for appropriate treatment' category has high levels of medication rate as many as 19 people (42.2%). In the research result, there are still families with the implementation of family health task 'taking decision for the appropriate action' in the less category, having low level of drug adherence compliance rate as many as one person (2.2%). The result of statistical analysis with Spearman Rho correlation test shows relationship between the implementation of family health task 'take decisions for appropriate action' with medication adherence of pulmonary tuberculosis patients (Table 4).

Implementation of family health task 'taking care for sick family members' in the good category has a high adherence in the drinking category as many as 21 people (46.7%). In the research result there is still family with family health task implementation 'taking care for a sick family member' in the enough category, but having low medication adherence level, as many as one person (2.2%). The results of statistical analysis with Spearman Rho correlation test found there is a relationship between the implementation of family health task 'taking care for a sick family member' with medication adherence in pulmonary tuberculosis patients. Implementation of family health task 'modifying a healthy environment' has

high categories of medication adherence as many as 16 people (35.6%). In the research result, there are still families with the implementation of family health tasks in the enough category, but the level of medication adherence is low as many as one person (2.2%). The result of statistical analysis with Spearman Rho correlation test showed that there was a relationship between the implementation of family health task 'modifying a healthier environment' with the adherence of taking the medicine for pulmonary tuberculosis patients. Implementation of family health task 'utilizing good health care facilities' has a high level of adherence to taking medication category as many as 21 people (46.7%). In the research result, there is still family with family health task implementation 'utilize health care facility' in the enough category, but low level of adherence of medication as many as one person (2.2%). The results of statistical analysis with Spearman Rho correlation test found that there is a relationship between the implementation of family health task 'utilize the available health care facilities' with the adherence of taking medication for pulmonary tuberculosis patients (Table 4).

DISCUSSION

Relationship between family health tasks implementation and medication adherence

The results of the study reveals a significant relation between family task implementation and patient adherence in taking medication. The adherence in taking medication will increase when the patient has the support from the other family members during treatment. In relation to the study, results declared that compliance in treatment will increase when patients get help from the family (Ramizer cited in Maulidia, 2014). The family is the first and closest unit to the patient, the family knows about the condition

of the patient's illness as well as most often communicates with the patient. Open and two-way communication in the family will greatly support the TB patient, reminding each other and motivating the patient to continue the treatment can obtain the healing process. The family role in TB patient care can be a good social support for each family member (Hannan and Hidayat Syaifurahman, 2013).

It was found that the implementation of good category family health tasks mostly has high levels of medication adherence, but there is also the implementation of family health tasks in the enough category to have low adherence level of medication. The condition is due to the factors that underlie compliance behavior, not only from family factors alone, but many other factors become influential, for

example, from an individual's factors themselves. An individual who has an unhealthy behavior, even though his or her family's support is good, will still have an effect on the level of medication adherence.

In this study, the family task implementation which was mostly good was caring for the sick family member, while the tasks about knowing family health problem and environment modification were less. The less understanding about those problems will result in the lower achievement of family task implementation in caring for a family member with TB. It's also proven by Freadman (2010 cited in Nurhidayati, Dhian, & Khoirunisa,2016) who stated that families have a role to carry out healthcare practices, namely to prevent the occurrence of health problems and care for family members who are sick.

The ability of families to carry out healthcare or maintenance can be seen from family health tasks carried out. Families who can perform good family health tasks means they are able to solve health problems that exist in family members. The role of the family in the implementation of good family health tasks is a powerful motivation or support in encouraging patients to seek treatment regularly as recommended (Pare, Amiruddin and Leida, 2010).

Research conducted by Herawati (2011) states that the family has an important role in the prevention of transmission of TB disease. Green states that the health of a person or society is influenced by two factors, namely behavioral factors and environmental factors. One's own health behavior is influenced by three factors, namely predisposing factors, enabling and reinforcing. Predisposing factors are internal factors that exist in the individual, enabling factors are supporting factors that encourage the realization of healthy behaviors such as healthcare facilities, while reinforcing factor is a strengthening factor such as support from family, teachers, community leaders, health workers and others (Nursalam, 2014).

The health behavior of TB patients in terms of medication adherence is also influenced by some factors. One of the important factors that plays an important role in the formation of patient medication behavior of pulmonary tuberculosis patients is the existence of family support, which can be evaluated through the implementation of family health tasks. Family support greatly supports the success of one's treatment by always reminding the patient to take medication on a regular basis, providing good care during the patient's treatment process, giving understanding and passion to the patient to remain diligent and regular in treating. The presence of family health and duties and tasks will have a psychological impact on patient compliance in the treatment process. Families who have been able to perform family health tasks well will establish good health behavior also, which in this case is behavior of medication adherence.

Relationship between family health task implementation: recognize health problems in the family and medication adherence

Recognizing family health issues is very important, because family health cannot be ignored (Ayuningtiyas, 2013). The family acts as the first to recognize a health problem in one of the family members. Health problems in the family can be resolved immediately if the family is able to recognize the health problems experienced by one member of the family.

Recognizing family members' health problems is a prelude to identifying family needs according to the situation (Kausar, Herawati and Pertiwiwati, 2015). The health of family members is very important to note. Health can be a great resource to meet the welfare of each family member. Families should be

able to understand every health problem that occurs in family members even though it is a small thing. The slightest changes experienced by family members will be a concern in family decision-making. The better the family's ability to familiarize themselves with family health problems the easier it will be for families to overcome the health problems experienced by a family member (Handayani, 2014).

Family ability to recognize health problems is not only in the context of the disease alone, but the family must also be able to recognize how the treatment process is, the problems that may occur during the treatment process, prevention and what are likely to occur if the lung TB patient does not undergo the treatment process that has been established. Families should be aware that long-term TB treatment processes will make TB patients feel bored with their treatment, so the family is expected to motivate and act as a supervisor in the patient taking the medicine in order to keep the patient obedient in taking the medicine (Marwansyah, 2012)

The result of the research showed that most TB patients' family's ability in Polyclinic of Pulmonary Disease in Haji General Hospital, Surabaya in recognizing health problem of family members is in the enough category (55.7%) with medication compliance level mostly in the medium category (28.9%). This is in accordance with Handayani's statement (2014) that the family's ability to familiarize themselves with family health issues will affect the outcomes of family problem solving.

The family's ability to recognize family health problems is one of the processes of gaining knowledge. Knowledge is influenced by two factors: internal factors and external factors. Internal factor includes education. The educational level of a person will have an effect on the understanding of an experience and stimuli provided through learning and other media. Knowledge will affect one's behavior as intermediate impact of the given stimulus (Zulfitri, Agrina and Herlina, 2012). Wahyudi, Upoyo, and Kuswati (2008) also stated that the higher the education of a person, the better the knowledge related to health problems. The results obtained data that most of the family education is high school (46.7%), the level of education is not high, but also not classified as low. This is what causes the family's ability in knowing the health problems of family members to still be in the enough category.

Recognizing the health problems of family members is an early stage to determine the next action to address the health problems experienced. The family's ability to familiarize themselves with family health issues can help families establish what measures are appropriate for family members in order to improve their health status. If the family health issues, particularly in TB patients, then they will consider the possibilities that may occur during the treatment process so that they can anticipate any problems.

Relationship between family health task implementation: taking decisions for appropriate treatment and medication adherence

The family is the primary key in decision-making and therapeutic care at every stage of sick family members (Setiadi, 2008). The family's ability to make the right decisions is the primary family effort to seek appropriate help according to family circumstances, taking into account who among family members has the ability to perform this task. Family health measures are expected to be appropriate to family circumstances (Marwansyah and Sholikhah, 2015). The family's ability to make the right decisions has an impact on the adherence of the pulmonary tuberculosis patient's medication. The accuracy and speed of the family in decision-making will affect the healing rate of TB patients. The sooner the family takes the decision, the sooner the family overcomes the health problems experienced by family members, in this case related to the adherence of taking the medicine for pulmonary tuberculosis patients (Kausar, Herawati and Pertiwiwati, Marwansyah and Sholikhah (2015) also stated that the ability of families to make good decisions can have a positive impact on ailing family, while, if the ability of the family is less able to negatively impact a sick family member, the sufferer may feel unnoticed.

Wahyudi et al. (2008) explain that, in the implementation of this decision-making task, the family will feel disturbed by the illness experienced by the patient; therefore, the family is rich to find the right treatment for the patient so the patient will recover from his illness. The family also strives to keep an eye on patients in undergoing a prescribed treatment program so that the treatment runs smoothly and the patient becomes obedient so that will accelerate the healing of the disease.

The family's ability in decision-making for appropriate action in this study was good (53.5%). It was also shown by the adherence of good or high TB drug patients (42.2%). These data suggest that the more accurate and quicker the decisions taken by the family will increase the compliance of TB patients in taking OAT drugs.

Decision-making for appropriate action can help the family in resolving family members' health problems. The family's ability to interpret the illness experienced by family members is influenced by the family's experience of the disease. If the family has been able to recognize the illness suffered by family members, then the family will be able to decide and take the attitude to overcome the illness experienced. Similar to TB patients, if the family has been able to recognize TB disease, including the old treatment process, the family will be able to make decisions when problems occur in patients during the treatment process.

Relationship between family health task implementation: taking care for sick family member and medication adherence

The main function of the family is family care, where the family provides preventive health care and jointly cares for the family members who are sick. The ability of the family in carrying out healthcare or maintenance can be seen from the task of family health that it does (Mubarak, Chayatin and Santosa, 2010). Setiadi (2008) explains that the family, in carrying out its functions, must understand about the illness experienced by family members, know the nature and development of care needed, know the sources in the family, know the existence of facilities needed for care and family attitudes toward sick family members. The family can perform simple maintenance in accordance with the ability, whereby the care of this family can be attempted to prevent side effects or complications of the disease to a minimum.

Notoatmodjo (2003) states that, after someone knows the stimulus or health object, then they will implement and practice what they know. When families are aware of the health problems of their family members, families can help family members take proper care of the health problems experienced.

The result of the research shows that the family health task that has been done well is taking care of a sick family member. This is because the family and patients of TB who seek treatment in Polyclinic of Pulmonary Disease in Haji General Hospital Surabaya always get assistance from the nurse on duty. The family always asks the nurse if problems occur or there are complaints during TB treatment. Nurses in Pulmonary poly, General Hospital Haji Surabaya also always provide health education on how to care for pulmonary tuberculosis patients to overcome the complaints that occur during treatment.

Families in caring for pulmonary tuberculosis patients should know about pulmonary tuberculosis and treatment programs that the pulmonary tuberculosis patient must undergo. In the treatment process, pulmonary tuberculosis patients are required to take many drugs, some of which have various side effects. Drug side effects that are too heavy will make TB patients reluctant to take the medicine again because they think it feels worse when taking the medicine. The family's ability to care for pulmonary tuberculosis patients has a major impact on the family's ability to cope with the side effects experienced. The better the family ability to overcome the side effects of taking medicine in pulmonary TB patients, the better the willingness of TB lung patients to complete the treatment program. The high motivation of the family with proper care will improve patient adherence in the prescribed treatment.

Relationship between family health task implementation: modifying a healthy environment and medication adherence

Modifying the environment is identical to how to make the environment a therapeutic place for patient recovery. In addition to the physical environment, the psychological supportive environment for sick family members also needs attention (Effendi and Makhfudli, 2009).

Modifying the environment to ensure family health is also important in family health tasks, as the health of family members is influenced by lifestyles, stress and the environment. Family health can be guaranteed by taking into account the environmental factors of residence (Handayani, 2014). Modifying the environment can help in the care of family members who experience health problems, in the form of home hygiene and creating comfort in order to rest in peace without any interference from outside. Health improvement and maintenance is essential, especially through the commitment and modification of the environment and family lifestyle. This will increase the role of the family in carrying out its responsibilities to the health of family members (Setiadi, 2008)

The ability to modify a good environment will minimize transmission of TB disease to other family members. Maintaining a healthy and conducive home environment will help TB patients to maintain their body resistance so that they can avoid other diseases during their treatment program. If a TB patient is suffering from another disease, it will allow them to take other medications. This will increase the amount of drugs consumed by patients, so it tends to potentially cause psychological problems in the patient, which will affect the patient's compliance in taking the drug. Therefore, families are required to have good skills in modifying a healthy environment for TB patients in order to ensure better adherence to TB drug treatment.

Relationship between family health task implementation: utilizing health service facilities and medication adherence

Family perception about healthy pain is closely related to behavior seeking for treatment. Family responses when there are family members who experience family health problems are very varied, ranging from not doing anything with the excuse not to interfere, performing certain actions such as treat yourself, seeking traditional medical facilities, finding drugs in drug stalls, seeking treatment to service facilities of modern health organized by the government or private, to seeking modern treatment organized by practicing physicians. This will affect whether or not health facilities are available (Notoatmodjo, 2007)

Pulmonary tuberculosis is a disease with a lengthy period for the healing process, that is patients should consume drugs regularly and on time. If this is not the

case, then the healing process will experience obstacles, or the other possibility is that there can be resistance to TB drugs (MDR-TB). Resistance to TB drugs will cause TB patients to repeat the treatment process. The process of treatment will be extended longer, the number of drugs consumed will also be increase. This condition will lead to problems in the psychological condition of the patient that will lead to non-adherence with medication (M, Rohmah and Wicaksana, 2015).

Utilizing health care facilities needs to be done, not only to maintain the health stability of pulmonary TB patients, but also to ensure that drug taking is done on time. Often the ability of families to reach health facilities becomes an obstacle for families to bring TB patients to health facilities. It also relates to the accuracy of pulmonary TB patient drug preparation (Handayani, 2014)

The family as a patient's medicinal overseer should ensure that patient drug taking should not depart from the schedule set by the health worker. Delay in taking drugs will make the patient late also in taking the medicine, so if left continuously it will lead to resistance to TB treatment. This will make the TB patient repeat the treatment process with increased number of medicines and longer time span, which will make the patient feel bored because they have to consume drugs continuously. This condition will affect patient compliance in taking OAT drugs. Therefore, the family should be able to utilize the health service facilities that are well available to support the cure of patients with drug medicine in the high category.

CONCLUSION

The results of data analysis with the Spearman Rho trial showed that there was a significant relationship between carrying out family task and medication adherence of TB patients. Adherence to medication will increase when patient get help from family. The family is the first and closest unit to the patients, the family knows about the disease, and also the patients and is who most often communicates with the patients. Open and two-way communication within the family will greatly support TB patients; asking for one another and motivating help to continue treatment can improve the healing process. The role of the family in the care of TB patients can be a social support for family members.

Implementation of family health tasks of pulmonary tuberculosis patients who seek treatment at Pulmonary poly General Hospital Haji Surabaya is mostly in the good category. Medication adherence of pulmonary tuberculosis patients treated in Pulmonary poly General Hospital Haji Surabaya is included in the category of high compliance. Family health tasks in caring of pulmonary tuberculosis patients have a significant relationship with the level of medication adherence of pulmonary tuberculosis patients in Pulmonary poly General Hospital Haji Surabaya. Family health task 'recognizing the health

problems of family members' has a significant relationship with the medication adherence of pulmonary tuberculosis patients who seek treatment at Pulmonary poly General Hospital Haji Surabaya. Family health task 'making decisions for appropriate action' has a significant relationship with medication adherence of pulmonary TB patients treated at Pulmonary poly General Hospital Haji Surabaya. Family health task 'taking care for sick family members' has a significant relationship with the medication adherence of pulmonary tuberculosis patients who seek treatment at Pulmonary poly General Hospital Haji Surabaya. Family health task 'modifying the environment' has a significant relationship with the medication adherence of pulmonary tuberculosis patients who seek treatment at Pulmonary poly General Hospital Haji Surabaya. Family health task 'utilizing available health care facilities' has a significant relationship with medication adherence of pulmonary TB patients treated at Pulmonary poly General Hospital Haji Surabaya.

Fear of Falling Among the Elderly in a Nursing Home: Strongest Risk Factors

Anastasia Putu Martha Anggarani and Raditya Kurniawan Djoar

STIKES Katolik St. Vincentius A Paulo, Surabaya, Indonesia

ABSTRACT

Introduction: The aging process causes a decrease in physical abilities which can cause fall events. Fall events are influenced by fear of falling. Some risk factors of fear of falling were age, gender, balance while walking, use of a walker, depression and a history of previous falls. This study aim was to identify risk factors related to fear of falling among the elderly in nursing home.

Methods: A cross-sectional study was used in this study. Respondents were elderly aged ≥60 years, can communicate well, able to read and write and not being sick which causes balance disorders and pain when walking. Respondents totaled 155 obtained by proportional random sampling. A questionnaire was used to retrieve data such as age, gender, use of a walker, depression, previous fall history and balance walking.

Results: The results showed a significant relationship between all of these risk factors with the fear of falling (p <0.05) and the power of significance for each variable was different. The age variable was power significance 0.228, gender C = 0.2, previous fall history C = 0.374, use of a walker C = 0.367, balance walking C = 0.355 and depression rs = 0.196. There are three risk factors most closely associated with fear of falling in terms of balance walking (B = 1.424 Exp(B) = 4,153), use of a walker (B = 1,365 Exp(B) = 3,914) and previous fall history (B = 1.425 Exp(B) = 4.159). These factors had strength of 27%.

Conclusion: Balance walking, use of a walker and previous fall history were the strongest risk factors.

INTRODUCTION

The aging process causes a decrease in physical ability and further can cause the incidence of fall, especially for the elderly. The number of falling in the elderly is quite high, at least 28% -35% of 65-year-old people fall every year and the number increases to 32% -42% in the elderly over 70 years (World Health Organization, 2007). Fall events are influenced by several factors, one of which is the personal factor of fear of falling. As to psychological status of fear of falling, up to 70% of recent fallers and up to 40% of those not reporting recent falls acknowledge the fear of falling (25,38,55). Up to 50% of people who are fearful of falling restrict or eliminate social and physical activities because of that fear (WHO, 2004).

Fall events are influenced by several factors, one of which is the personal factor of fear of falling. Fear of falling is an internal phenomenon or anxiety associated with falls that can affect a person's level

of dependence which results in a decrease in function when doing activities. Fear of falling is a residual symptom of falling, but can also occur in people who have never fallen. This incident occurs above 60% in the elderly aged 60-79 years (Howland, 1998). Fear of falling can affect quality of life for the elderly and increase the risk of falling through the reduction of physical activity, confidence, strength, and balance. Fear of falling can reduce balance control and reduced the confidence to prevent falls, further increasing the incidence of falls for the elderly (Public Health Agency of Canada, 2005).

Fear of falling is feeling anxious when walking or mobilizing normally or normally, it can cause falls (Greenberg, 2011). The current study showed around 26% -55% of elderly people living in the community were fearful of falling, and 40% -73% of the elderly who had fallen had fear of falling (Howland, 1998). In many ways, the fear of falling potentially causes restrictive movement, especially

for the elderly. That condition can decrease the independence of the elderly in daily activities (Murphy, 2002), decreased quality of life of elderly and decreased social interaction (Austin et al., 2007).

The prevalence of fear of falling is in line with age (Scheffer et al., 2008). Aging will lead to physiological changes in the body's systems, such as the musculoskeletal, cardiovascular, respiratory, nervous, sensory and other organ functions (Narinder & Verma, 2007). Because of physiological changes during the aging process, the elderly will have difficulty maintaining balance while performing activities. This situation can produce fear of falling during a functional activity.

Several studies of fear of falling have identified the prevalence of more women (Susan et al., 2002). In one study conducted on 1000 women over three years, more than one-third of the samples reported fear of falling and increased 45% after three years (Lach, 2005). The fear of falling is also influenced by the ability to maintain balance while walking (Jacobs & Fox, 2008). People with impaired balance have lost confidence to rest with the feet, especially when walking (Fletcher & Hirdes, 2004; Kumaret al., 2008)) so that it will increase the fear of falling.

Psychological conditions, especially depression, also become one of the risk factors in fear of falling. Depression has a strong relationship with the fear of falling and can cause the limitations of physical and social activity (Jung, 2008). When the ability to do activity is decreased, elderly people will feel not confident and increase further fear of falling. Depression can also make people less secure about their physical abilities, thus causing fear of falling (Legters, 2002).

Several studies have shown a positive relationship between fear of falling and a previous fall history. A person who often experiences a fall will increase the incidence of fear of falling (Jung, 2008). Elderly people who have fallen are also more difficult to maintain balance as they perform their functional activities for fear of falling (Kumaret al., 2008). Elderly people who feel fear of falling will protect themselves by using walking aids to reduce the fear (Victorian Quality Council, 2004). However, the elderly dependency on walking aids will also increase the fear of falling.

Several factors have a positive relationship with fear of falling; therefore, through this study, we want to identify the strongest risk factors that have been mentioned. So, it will be very helpful in determining the intervention, especially sports activities appropriate for the elderly who can support the maintenance of independence, function, health, and safety for them so it can be used as a preventive effort to reduce the incidence rate of fall in the elderly (Greenberg, 2011).

MATERIALS AND METHODS

This study was carried out at private and government nursing homes, St Yosef nursing home, Surya nursing home, Usia nursing home, Griya Wredha nursing home, Anugerah Surabaya nursing home, and Yayasan Cinta Kasih Ibu Teresa, between 1 March and 29 May 2016. The study protocol was approved by the ethical committee on health research, Faculty of Medicine, Airlangga University, Indonesia. Informed consent was obtained from all of the respondents.

This study was conducted at 155 elderly determined by a proportional random sampling technique. Independent variables in this study are age, gender, previous fall history, use of a walker, depression status, and balance ability, while the dependent variable is fear of falling. The data were obtained by using questionnaire. The questionnaire containing questions about age, gender, previous fall history and use of a walker. To fill in the age data, the respondents fills his / her age in the questionnaire in year, gender, for the data of previous fall history, respondents select "yes" or "no" items in the questionnaire, and for the data of the use of the walker, respondents select item "yes" or "no" in the questionnaire.

To obtain the fear of falling data, we used the Questionnaire Modified Fall Efficacy Scale Indonesia Version with content validity item in the range of 0.857 - 1 (valid value> 0.78), while the Sum-Content Validity Index obtained the result 0.93 (valid value> 0.9) with Cronbach's alpha value 0.948), and to obtain depression data we used the Indonesian version of the geriatrics depression scale (GDS) questionnaire with Cronbach's alpha value of 0.88 (Himawan, Rinawaty, & Wirawan, 2014), in addition, we used the Time Up and Go Test (TUGT) with interrater of 0.94 and intra rater of 0.95 to obtained balance walking data (Asnandra, 2009).

The data were recapitulated, entered into the SPSS program and analyzed. Spearman test was used to identify correlation for age, depression, and fear of falling and the other data used Contingency Coefficient to identify the correlation between gender, previous falls history, use of a walker, balance ability with fear of falling. To identify the risk factor, binomial logistic regression was used.

RESULTS

Characteristics of respondents in this research are average 76 years with a percentage equal to 70.3% and female. Of the 155 respondents it was found 58.1% had experienced a fall. As many as 65.2% are not depressed. Respondents in this study, as many as 65.8%, had a risk of falling and 74.2% of them did not use a walker. A total of 49.7% of respondents have high concerns about falling (Table 1).

Table 1. Demographics (n: 155)

Variable	Sub Group	Mean±SD/n(%)
Age		76.3±8.02
Gender	Male	46 (29.7%)
	Female	109 (70.3%)
Previous fall history	Yes	90 (58.1%)
	No	65 (41.9%)
Use of a walker	Yes	40 (25.8%)
	No	115 (74.2%)
Balance walking		22.3±14.6
	Risk of Falls	102 (65.8%)
	No risk of Falls	53 (34.2%)
Depression		8.5±5.1
	Normal	101 (65.2%)
	Mild Depression	50 (32.3%)
	Moderate Depression	4 (2.6%)

Table 4. Chance of Fear of Falling

Risk of Falls	Use of a walker	Previous fall history	% Chance of Fear of Falling
No	No	No	10.76%
No	Yes	No	32.06%
No	No	Yes	33.36%
Yes	No	No	33.39%
No	Yes	Yes	66.23%
Yes	No	Yes	67.57%
Yes	Yes	No	66.23%
Yes	Yes	Yes	89.07%

Spearman test was used to identify correlation for age, depression, and fear of falling and the other data used Contingency Coefficient to identify the correlation between gender, previous fall history, use of a walker, and balance ability with fear of falling. The correlation analysis in this study showed that there was a moderate correlation between the previous fall history and the fear of falling (C = 0.374; p = 0.000), the use of walking aids with fear of falling (C = 0.367, p = 0.000) and the balance walking with fear of falling (C = 0.355; p = 0.000) (Table 2)

Multivariate analysis in this study used a binomial logistic regression test. We used this test because the correlation test of risk factors fear of falling to fear of falling is not strongly related and we assume the possibility of any relationship between each risk factor. The previous fall history, the use of walkers and the current balance is the strongest risk factor for fear of falling (Cox & Snell R Square = 0.276). Respondents experiencing one of these three risk factors risk an average of four times more with high fears of falling (Exp (B) = 3,914-4,159) (Table 3). Respondents who do not have a risk of falling, do not use walking aids and do not have a previous fall history still have a chance of fear of falling by 10.76%. Respondents who are at risk of falling, using walking aids and having a previous fall history have a high probability of falling 89.07%. To identify the chance of power independent variable to the dependent variable, the researcher using the formula $P:1/1+e^{-y}$. (Y= -2,116+1,425 balance ability+1, and use of a walker +1, previous fall

history. The formula used by researchers has a precision of 74.8%.

Remarks:

DISCUSSION

This study showed 58.1% of respondents had a history of previous falls. The result of the correlation analysis p = 0.000 r = 0.374 indicating that the previous fall history has a moderate strength relationship with fear of falling. The logistic regression analysis test showed the result of significance p = 0.000 with the positive direction indicated by the value of B = 1.423. This is by the theory that a person who often experiences a fall will increase the incidence of fear of falling (Jung, 2008). When viewed from the chances of respondents who have a history of falling and experiencing high fears they will fall, this obtained data of 33.3% and 76.62% of respondents who have a history of falls have high worries they will fall. Other studies with elderly respondents also reported that there was a significant correlation between previous fall history and fear of falling (Lopes, Costa, Santos, Castro, & Bastone, 2009). The fear of falling can be described depending on the experience of the previous fall and the increased fear of falling with the fall type (Arken et al., 1994). Fall events that cause serious injury further increase the fear of falling (Salkeld et al., 2000). Elderly people who have experienced a previous fall not only impact on their physical condition, but have an impact on the psychological conditions in which they will feel traumatized by such unpleasant events and afraid to fall again when they do the activity. This condition will have an impact on the decline in social activity and confidence.

This study has the result explain that although respondents who never fall but they have risk of falls and using a walking aid, they have a chance 66.23% fear of falling (Table 4). This is in line with previous research by Lopes et al. (2009) where the incidence of fear of falls occurred by 12% -65% in the elderly who live in the community, aged over 60 years and have no previous fall history. The results obtained in this study indicate that most respondents who have a fear of falling do not have a previous fall history (Lopes et al., 2009). This condition can occur because the fear of falling is a multifactor event, so that not only the previous fall history can cause fear of falling. Elderly people who do not have a previous fall history may experience fear of falling. This fear can be a safeguard to be more careful to avoid the risk of falling, but also can be a risk when it results in limitations and lack of confidence when doing activities.

The previous fall history is one of the biological factors of fear of falling. To determine the appropriate intervention in this risk factor, it is

necessary to examine the type of activity, the time of the fall, the frequency of fall, the injury suffered and the symptoms at the time of fall. If the elderly have a history of falling due to unsafe environmental causes for the elderly to walk, then appropriate intervention is to change the environment to be safe for the elderly, for example: to give a handle in every aisle used by the elderly to walk so that the elderly remain confident not to fall. Interventions that can be done in the elderly with a history of previous fall include trying to stay active, always positive thinking, take care of yourself and do relaxation exercises (Shaw, 2010).

For these three things, balance is one of the key moves (Allison, 2001). Balance, strength, and flexibility are needed to maintain good posture. These three elements are the basis for realizing a good road pattern for each individual. Important mechanisms for each individual to have a good balance involve the peripheral nervous system, proprioceptive (sense of joint position), vestibular and cerebral and visual (vision) (Skelton, 2017), otherwise known as postural control, which is the ability to maintain balance and orientation in the gravitational environment. According to Lopes et al. (2009), postural control consists of three components, peripheral sensory system, central system, and effector system, and the elderly will experience a decrease in function, as well as peripheral nerves. Central processing runs slowly as well as in the interpretation and sensory information of the system and recruitment of motor planning, and careful environmental responses. Peripheral nerves, skeletal muscle mass and muscle strength decrease in function causing postural control to be slower and weaker. This decrease in function will disturb the balance, which will ultimately lead to a greater risk of falling (Jette, 2012).

In this study data obtained 65.8% of respondents have the risk of falling. The result of the correlation analysis is p = 0.000 r = 0.355, which shows that the current balance has a medium relationship with the strength of the relationship. The logistic regression analysis test showed the result of significance p = 0.001 with the positive direction indicated by the value of B = 1.425. Research conducted by Boyd and Stevens (2009) shows a relationship between decreasing balance and fear of falling. Posture control, voluntary movement stability, and reaction maintain balance when being subjected to outside interference is the basis for maintaining balance. Postural control involves the integration of sensory, nervous, and musculoskeletal systems, so the center of mass remains at bases of support and center of gravity moves along with a change in the base of support so that balance can be formed (Miyamoto, Lombardi, Berg, Ramos, & Natour, 2004).

Another study reported that 78.91% of respondents experienced partial independence during transfer, 50.34% indicated a fear of falling through the tandem gait test (correlation r = 0.457)

and 31.39% decreased equilibrium (correlation r = 0.44248) (Lopes et al., 2009). This is in line with this study that there is a relationship between the current balance and the fear of falling. Fear of fall is the result of the recruitment of agonist and antagonist muscle work while maintaining poor posture, abnormal road patterns, poor balance strategy, depending on assistive devices that ensure stability and increased risk of falls in the elderly. When a person is feeling unbalanced when doing activities, especially walking, this will directly make the individual afraid to perform activities because of changes in the balance that can consciously cause a fall when forced to move. Likewise, in the elderly, physical changes are closely related to the balance in walking. The chance of respondents experiencing high concerns they will fall in respondents who have a risk of a fall is 33.39%. Medical conditions associated with a disturbance of equilibrium greatly affect the increased fear of falling because people with impaired balance have lost the confidence to rest with the foot, especially when walking (Kumar, Venu Vendhan, Awasthi, Scholar, & Tiwari, 2008). Therefore, it is necessary to identify the main factors causing the imbalance so that appropriate interventions can be given to improve the balance of the elderly.

To determine the appropriate intervention of this risk factor, an examination consisting of a path pattern examination, balance and joint function on the lower extremities is required. One of the interventions that can improve balance is tai chi gymnastics. This is shown in a study conducted by Scheffer, Schuurmans, van Dijk, van der Hooft, and de Rooij (2007) which found that there is an increase in balance during activity. Tai chi is a sport that contains slow, rhythmic movements, many involving trunk movements, weight transfer, coordination, and pedestrian refinement. This gymnastic activity is performed for 60-90 minutes for two sessions per week.

This study shows 25.8% of respondents using road aids. The result of the correlation analysis p = 0.000 r = 0.367 indicates that the use of the walker has a relation with the medium strength of the relationship. The logistic regression analysis test showed the result of significance p = 0.006 with the positive direction indicated by value B = 1.365. Opportunities of respondents using of road aids experienced high concerns about falling (32.06%). The elderly use walking aids for various reasons, namely as a therapeutic tool to train post-injury walking skills, the elderly with neurological disorders, and to further reduce the fear of falling (World Health Organization, 2007). The use of a walker has a protective effect on falls in the elderly as it helps elderly people with mobility limitations when engaging in activities with disturbances from the environment (Rayel, Land, & Gutheil, 1999). Elderly using a walker already have concerns about falling if they do activities. This is in line with the

theory so they compensate by using a walker to reduce the fear of falling.

This is in line with research conducted by Multani andc Verma (2007) in 43 elderly people (≥ 60 years) where 22 people (51%) used a walker at least one year. The reason for the respondents using the walker was because they were afraid of falling as much as 54.5%, while the other reason was finding security (27.3%), and habituation following surgery/injury (18.2%).

This study also obtained the data of respondents who do not use a walker, but have a high concern they will fall, as many as 45 people (58.44%). Elderly do not use walkers because they feel embarrassed / considered disabled, elderly and feel by using a walker it will restrict its activity because the use of a walker can affect the pattern of the road by inhibiting swing pattern, affect posture, reduce road speed, step length and swing time, and stance time (World Health Organization, 2007). It will cause more fear of falling. Besides, the elderly judge that the environment around them does not support them to use the walker. Another thing that causes those who do not use the walker, but still experience high worries they will fall, with 32 respondents have a history of falling before, 32 people have a risk of falling, and 22 people have a history of previous fall and have the risk of falling.

Some elderly people have difficulty when using a walker. Therefore, the should be trained in advance in the use of a walker, especially in the elderly, on how to use the right aids so that the elderly are confident in using the tool so that the fear of falling can be reduced (Bradley & Hernandez, 2011).

This study reported that the probability of experiencing heightened fear of fall over those who do not have a risk of falling / balancing when walking well, not having a previous fall history and not using a walker is 10.76%. This concern can be a protective order to be more careful to avoid the risk of falling during the move.

Opportunities experiencing heightened concerns they will fall over those who have had a previous fall history and use the walker is 66.23%. One study that. from 199 respondents. reported respondents (28.4%) often experienced a fall in the last 12 years, eight respondents (4.1%) had experienced a fall of one time to cause injury and 32 respondents (16.2%) never experienced a previous fall without causing injury. Respondents who had experienced the fall using a walker and experienced fear of falling (Roman de Mettelinge & Cambier, 2015). The elderly who have experienced a fall have low confidence when doing activities for fear of falling owned. To increase confidence to feel a sense of security while doing activities and avoid the risk of falling back, some elderly use a walker because it helps to maintain balance while on the move.

People who have a risk of falling / balancing on a bad run and using a walker have a chance of high worries will fall by 67.57%. The use of a walker indicates the occurrence of a balance disorder or

may cause one to lose balance due to an increase in attention requirement (Public Health Agency of Canada, 2005), and it can cause fear of falling.

People who have a risk of falling/balancing on a bad run and having a previous history of falling have a chance of high worries they will fall by 66.23%. Ability to maintain balance while on the move/walking is done by several systems in the body. When considering elderly experiencing a decline in anatomical and physiological functions, the ability will be reduced, resulting in the elderly often experiencing a fall during the move. Therefore, the elderly who have often experienced a fall because of balance going bad will experience the fear of falling to a higher extent.

According to this study, if people have a risk of falling / balancing when walking is bad, having a history of previous falls and using a walker, they will have a chance of experiencing high worries they will fall by 89.07% (Table 4). This is because of the three things are the most dominant factors in the fear of falling. The elderly having a poor balance will feel insecure when using foot as a pedestal. This causes an increased risk of falling in the elderly. The elderly who had fallen had a sense of trauma and confidence reduction during the move, so used a walker. The use of a walker will also cause the elderly to have unusual road patterns, reduce swing while walking, affect posture, reduce road speed, length of step and stance time, and then will increase worries of fall.

CONCLUSION

The strong predictor of the fear of falling in the elderly was the use of walkers, balance and previous fall history. Therefore, based on this study people who have responsibility in the nursing home have to provide regularly activities such as gymnastics which can improve the balance of the elderly, also provide consultation for the elderly to be able to increase self-confidence, especially for those who have a history of previous falls, and modify the environment to add handrails in the area used by the elderly to reduce fears of falling.
